Experimental Methodology and Results

Selection of the number of cutpoints in MTEs

Conclusions

## AODE classifier I

- **AODE** is significantly better in terms of error reduction compared to the rest of semi-naive techniques.

- **MAP hypothesis:**

$$\operatorname{argmax}_{c \in \Omega_C} \left( \sum_{j=1, N(a_j) > m}^n p(c, a_j) \prod_{i=1, i \neq j}^n p(a_i | c, a_j) \right)$$

- Quadratic in learning and classification time.
- ✗ : **Only discrete variables.**

Conclusions

# Motivation

- A BN assume **all** the variables are **discrete**.
- **Large amount of methods** developed to solve problems with **discrete variables**.
- It is common the **coexistence** of **discrete** and **continuous** variables in the same problem.
- Direct solution → **discretization**.
  - ✗ : Unavoidable lost of precision.
  - ✗ : Which discretization method should we choose?.
- Some alternative solutions:
  - 1 **Conditional Gaussian Networks (CGNs)**: GAODE and HAODE.
  - 2 **Kernel-based distributions**: high costs, problems in inference.
  - 3 **Mixtures of truncated exponentials**: exact frame for working with hybrid nets.

Conclusions

## Previous proposals based on CGNs

- Proposals based on the assumption that for each configuration of the categorical variables, all the numerical attributes are **sampled from** a **Gaussian** density distribution.
- Despite this strong assumption, Gaussian distributions usually provide reasonably **good approximations** to many real-world distributions.
- **GAODE** and **HAODE** inherit AODE's graphical structure, but differ in the way the superparent attribute is managed.

# Performance of GAODE and HAODE

- According to previous experiments carried out [2]:
  - In numerical domains:
    - There is no statistical difference between GAODE and AODE in numerical domains.
    - HAODE is better than both of them.
  - In hybrid domains:
    - No statistical difference was found between the performance of AODE and HAODE.
    - Reconsider Gaussian assumption.

# The MTE model (Moral et al., 01)

## Definition (MTE potential)

- $\mathbf{X}$ : mixed  $n$ -dimensional random vector.  $\mathbf{Y} = (Y_1, \dots, Y_d)$ ,  $\mathbf{Z} = (Z_1, \dots, Z_c)$  its discrete and continuous parts. A function  $f : \Omega_{\mathbf{X}} \mapsto \mathbb{R}_0^+$  is a **Mixture of Truncated Exponentials potential (MTE potential)** if for each fixed value  $\mathbf{y} \in \Omega_{\mathbf{Y}}$  of the discrete variables  $\mathbf{Y}$ , the potential over the continuous variables  $\mathbf{Z}$  is defined as:

$$f(\mathbf{z}) = a_0 + \sum_{i=1}^m a_i \exp \left\{ \sum_{j=1}^c b_i^{(j)} z_j \right\}$$

for all  $\mathbf{z} \in \Omega_{\mathbf{Z}}$ , where  $a_i, b_i^{(j)}$  are real numbers.

- Also,  $f$  is an MTE potential if there is a partition  $D_1, \dots, D_k$  of  $\Omega_{\mathbf{Z}}$  into hypercubes and in each  $D_i$ ,  $f$  is defined as above.

## Definition

An MTE-AODE classifier classifies an individual as in AODE, where all the probability functions involved are of class MTE.

- **Advantages:**

- (over GAODE) the underlying distribution is not assumed to be of Gaussian type, as MTEs are able to accurately represent the most common distributions.
- (over HAODE) there is no need to discretize the super-parent nodes, as the MTE mode allows discrete variables with continuous parents.

- **Disadvantages:** the learning phase is slower, as the parameters are adjusted iteratively following the algorithm described in [5].

- We can trivially extend this definition to the **MTE-NB** classifier as a particular case of MTE-AODE.

Conclusions

## Previous considerations

- Study the application of MTEs over a **large group of datasets** without individual parametrization.
  - 16 hybrid datasets.
- Can a general recommendation on how to best handle continuous attributes can be given?
  - So far, only studies on specific datasets.
- The **number of intervals into which the domain for a continuous variable is split** in an MTE potential.
  - In MTEs, **EF** discretization is applied **only to parent variables in a conditional distribution** represented by a mixed tree.
  - The domain of the variable that actually appears in the functional definition of the MTE potential in each leaf of the mixed tree is split taking into account the **inflection and extreme points** of the sample density.
  - Based on **empirical results**: trade-off between low complexity and high fitting power.
  - Equal frequency division with 5 and 10 intervals ((**EF5** and **EF10**) as in [6] and Fayyad & Irani (**F&I**)).
- 5x2 cross validation.
- Filters to replace missing values and remove useless attributes.

# Accuracy comparisons

Flores et al.

**Table:** Accuracy comparison between NB and AODE with MTE and the other algorithms. The bullet indicates significant performance applying the Wilcoxon test.

	Naive Bayes		AODE	
	MTE vs G	MTE vs D	MTE vs H	MTE vs D
EF5	11-5	7-9	9-7	7-9
EF10	10-6	5-11	8-8	●5-11
F&I	10-6	9-7	8-8	8-8

Conclusions

## Conclusions

- **Generalization of AODE** to all kind of datasets through **MTEs**.
  - Extensible to NB and other semi-naïve classifiers.
- ① The selection of the number of intervals is not trivial:
  - It is advisable to find the **optimum for every data set**, but also,
  - To find the **optimum for every domain** to partition in each leaf of the mixed tree independently, requiring a more sophisticated supervised “discretization” technique oriented to the estimation of MTEs.
- ② Time complexity:
  - The estimation of MTEs requires **more than EF** discretization.
  - This time **can be controlled**: limiting the number of exponential terms and playing with the maximum number of intervals into which divide the domain.
- Good **alternative to CGs** and **discretization** for some datasets.
