#### Abstract

Suppose that a random graph begins with $n$ isolated vertices and evolves by edges being added at random, conditional upon all vertex degrees being at most 2. The final graph is usually 2 -regular, but is not uniformly distributed. Some properties of this final graph are already known, but the asymptotic probability of being a Hamilton cycle was not known. We answer this question along with some related questions about cycles arising in the process. Key words: Hamilton cycle, hamiltonicity, random graph process, 2-process, probability, martingale, large deviation inequality, differential equation, graph.

## 1 Introduction

Suppose we begin with $n \geq 2$ isolated vertices, and add edges randomly one by one such that no multiple edges are created and that the maximum degree of the graph thus induced is always at most $d$, where $d \geq 1$ is a given integer. These random processes were studied in [5], where it was shown that when no more edges can be added, the number of edges is almost surely equal to the maximum possible number, $\lfloor d n / 2\rfloor$, as $n \rightarrow \infty$. In the case $d=2$, the final graph must be a collection of disjoint cycles, together perhaps with one isolated edge. This was studied in [6] in more detail and information about the distribution of cycles of bounded length in this graph was obtained. It was also shown that the expected number of cycles in total is at $\operatorname{most} 3+\log n$. In the present paper we study the long cycles in the final graph and answer several of the questions raised about 2-processes by Erdős (see [6]). In particular we compute asymptotically the probability that the final graph is just an $n$-cycle. This tells us the probability that the final graph is connected. For $d$-processes with $d \geq 3$, it was shown [7] that the final graph is connected with probability tending to 1 as $n \rightarrow \infty$.

We assume that a graph $g$ may have no multiple edges or loops, and denote its edge set by $E(g)$. We say that $g$ is 2 -maximal if every vertex has degree at most 2 , but no new edge can be added without violating this condition. The reason for this can be that every vertex, except perhaps one, already has degree 2 , or that there are only two vertices of degree less than 2, which are already adjacent. Formally, we define a 2 -process to be a sequence of graphs $\left(g_{0}, g_{1}, \ldots, g_{n}\right)$ on vertex set $[n]=\{1,2, \ldots, n\}$ such that the following (i)-(iv) hold for some $w \leq n$ :
(i) $\left|E\left(g_{t}\right)\right|=t, \quad t=0,1, \ldots, w$;
(ii) $g_{w}=g_{n}$;
(iii) $\emptyset=E\left(g_{0}\right) \subseteq E\left(g_{1}\right) \subseteq \cdots \subseteq E\left(g_{n}\right)$; and
(iv) $g_{n}$ is 2-maximal.

From (iv) it follows that the graph becomes 2-maximal at time $w=w\left(g_{1}, \ldots, g_{n}\right)$, which stands for the number of edges in the graph when no more can be added. The process remains static until time $n$, which is the maximum time a 2 -process can possibly run. Clearly $w=n-1$ or $n$. Property (ii) is included merely for the convenience of having all sequences of equal length.

A random 2-process is a probabilistic space whose elements are 2-processes with probabilities assigned as follows. Define $u_{t}$ to be the number of vertices of degree less than 2 (unsaturated vertices) in $g_{t}$, and $z_{t}$ the number of edges whose ends both have degree 1 (isolated edges). We assign the probability

$$
\prod_{t=0}^{w-1} \frac{1}{\binom{u_{t}}{2}-z_{t}}
$$

to the 2-process $\left(g_{0}, g_{1}, \ldots, g_{n}\right)$. It is convenient to think of $g_{t}$ as being formed at time $t$ by adding an edge $e_{t}$ to $g_{t-1}$, where $e_{t}$ is chosen uniformly at random from current available sites. Here an available site is a pair of unsaturated, non-adjacent vertices of $g_{t-1}$. The edges $e_{1}, \ldots, e_{n}$ of $g_{n}$ are in the order in which they appear in the process, where $e_{n}$ is left undefined if $w=n-1$.

We use upper case letters to denote random variables corresponding to the lowercase deterministic parameters. Thus, a random 2-process is denoted by ( $G_{0}, G_{1}, \ldots, G_{n}$ ), and $U_{t}$ and $Z_{t}$ are the numbers of unsaturated vertices and isolated edges at time $t$ respectively. From [5, Theorem 1.1] it follows that in a random 2-process $w=n$ occurs almost surely. In this case the final graph $G_{n}$ is 2-regular, and thus is a collection of disjoint cycles. If there is only one cycle, then $G_{n}$ is hamiltonian. The main result in this paper, namely Theorem 1 below, gives asymptotically the probability of the hamiltonicity of $G_{n}$. Throughout the paper the asymptotics is made as $n \rightarrow \infty$. In particular, a random 2-process has a property $Q$ asymptotically almost surely (a.a.s.) if $\lim _{n \rightarrow \infty} \mathbf{P}(Q)=1$. Denote

$$
\tau=\int_{0}^{\infty} \frac{\log (1+x)}{x e^{x}} d x
$$

so that

$$
\begin{aligned}
\tau & =\frac{\gamma^{2}}{2}+\frac{\pi^{2}}{4}-\sum_{k=1}^{\infty} \frac{2 k^{-1}+\psi(k)}{k \cdot k!} \\
& \approx 0.7452
\end{aligned}
$$

by [3, p. 530, eq. 6.], where $\gamma=\lim _{k \rightarrow \infty}\left(1+\frac{1}{2}+\cdots+\frac{1}{k}-\log k\right)$ is Euler's constant and $\psi$ is the digamma function.

## Theorem 1

$$
\mathbf{P}\left(G_{n} \text { is hamiltonian }\right) \sim \frac{c_{1}}{\sqrt{n}}
$$

where $c_{1}=\sqrt{\frac{\pi e^{\tau}}{2}} \approx 1.819$.
For random 2-regular graphs with uniform probability distribution, the probability of a hamilton cycle is easily computed from the results of Bender and Canfield [1] to be $\frac{1}{2} e^{3 / 4} \sqrt{\pi} n^{-1 / 2} \approx 1.876 n^{-1 / 2}$, which is slightly different from the 2 -process result above.

Theorem 1 is proved by obtaining a fairly precise estimate for the probability that the $t$-th edge $E_{t}$ completes a cycle. The graph $G_{n}$ is hamiltonian if and only if the first time this happens is with $E_{n}$. We obtain this estimate by determining some parameters of the process fairly accurately, namely the numbers of isolated vertices (also called isolates) and of isolated edges. This is done by showing that a.a.s. these numbers are approximated by the solutions of some differential equations, as in [6] and [9]. The interesting new feature of the present analysis is that we can demonstrate this approximation until very near the end of the process (see Theorem 4, stated in Section 2 and proved in Section 3), due to the attractive nature of the solution of the differential equation. This is a necessary
requirement in the present application, since the probability of forming a cycle at a given step increases throughout the process, to a constant value at the end, and therefore the end of the process plays an important role for hamiltonicity.

Our method has similarities with mean field theory used in statistical physics, where a complex interacting stochastic system is described by differential equations arising under the assumption that all the variables take their expected values. In this paper, we use conditional expectations and martingale arguments to make the heuristic mean field approach rigorous. In particular, this approximation works to near the very end of the process.

A simpler consequence of the analysis required for Theorem 1 leads to the following strengthening of [6, Theorem 3]. We use $X_{n}$ to denote the number of cycles in $G_{n}$.

## Theorem 2

$$
\mathbf{E}\left(X_{n}\right)=\frac{1}{2}(\log n+\log 2+\gamma-\tau)+O\left((\log n)^{-1 / 11}\right)
$$

where $\tau$ and $\gamma$ are as above.
Another point of interest in the evolution of a 2-process is the time when the first cycle appears. We denote this time by $T_{n}$. Again using little more than part of the proof of Theorem 1, we obtain the following result, where $c_{2}$ is a constant whose precise formula will be given in the proof.

## Theorem 3

$$
\mathbf{E}\left(T_{n}\right) \sim c_{2} n
$$

where $c_{2}$ is constant, $c_{2} \approx 0.829$.
The analysis required for Theorem 1 also gives rise to approximations of the probability that $G_{t}$ contains no cycles, for given $t$. See Figure 1 and the discussion at the end of Section 2.

The three theorems above answer Questions 6, 5 and 1 asked at the end of [6]. Probably the most interesting open problem remaining in this area is whether the final graph of this process is contiguous to a random 2-regular graph (see [8]). Unfortunately, the methods of the present paper are not strong enough to answer this.

## 2 Proofs

It was the analysis of the number of isolated vertices that led to the main results in $[5,6]$. Here we shall need more: sharp concentration not only of the number of isolated vertices but also of the number of isolated edges. Also we need knowledge of their behaviour for longer than in [5, 6]: we need good upper and lower bounds almost until the very end of the process. The proof of the concentration results will be deferred to Section 3. In

Figure 1: Approximate probability of no cycles after $x n$ steps
the present section, we motivate these concentration results and use them to prove the theorems.

Let $\mathcal{C}_{t}$ denote the event that $E_{t+1}$ creates a cycle when it is added to $G_{t}$, and $\overline{\mathcal{C}}_{t}$ its complement. Then we have

$$
\begin{equation*}
\mathbf{P}\left(G_{n} \text { is Hamiltonian }\right)=\mathbf{P}\left(\bigwedge_{t=0}^{n-2} \overline{\mathcal{C}}_{t}\right) \tag{2.1}
\end{equation*}
$$

(assuming $n \geq 2$ ). We use $Y_{t}$ to denote the (random) number of isolated vertices at time $t$. By counting vertex degrees, we know that the number of vertices of degree 1 in $G_{t}$ is $2\left(n-t-Y_{t}\right)$ and hence

$$
\begin{equation*}
Y_{t}+U_{t}=2(n-t) \tag{2.2}
\end{equation*}
$$

Since the connected components of $G_{t}$ are necessarily paths, cycles and isolated vertices, the number of paths of length at least 2 is $n-t-Y_{t}-Z_{t}$. Hence we have

$$
\begin{equation*}
Y_{t}+Z_{t} \leq n-t \leq U_{t} \tag{2.3}
\end{equation*}
$$

Note that $n-t-Y_{t}-Z_{t}$ is the number of edges which cause a cycle when added to $G_{t}$. Thus, given $G_{t}$, the probability of $\mathcal{C}_{t}$ is

$$
\begin{align*}
\mathbf{P}\left(\mathcal{C}_{t} \mid G_{t}\right) & =\frac{n-t-Y_{t}-Z_{t}}{\binom{U_{t}}{2}-Z_{t}}  \tag{2.4}\\
& =\frac{U_{t}-Y_{t}-2 Z_{t}}{U_{t}^{2}}\left(1+O\left(\frac{1}{U_{t}}\right)\right) \tag{2.5}
\end{align*}
$$

where the $O\left(1 / U_{t}\right)$ term is obtained by using $Z_{t} \leq U_{t}$ from (2.3).
The expected changes in $Y_{t}$ and $Z_{t}$ are given by

$$
\begin{gathered}
\mathbf{E}\left(Y_{t+1}-Y_{t} \mid G_{t}\right)=-\frac{2 Y_{t}}{2 n-2 t-Y_{t}}+O\left(\frac{1}{n-t}\right) \\
\mathbf{E}\left(Z_{t+1}-Z_{t} \mid G_{t}\right)=\frac{Y_{t}^{2}-4\left(2 n-2 t-Y_{t}\right) Z_{t}}{\left(2 n-2 t-Y_{t}\right)^{2}}+O\left(\frac{1}{n-t}\right) .
\end{gathered}
$$

See Lemma 2 in the next section for details. Thus, we will approximate $\mathbf{E}\left(Y_{t+1}-Y_{t} \mid G_{t}\right)$ by $f\left(t / n, Y_{t} / n\right)$, and approximate $\mathbf{E}\left(Z_{t+1}-Z_{t} \mid G_{t}\right)$ by $g\left(t / n, Y_{t} / n, Z_{t} / n\right)$, where

$$
\begin{gather*}
f(x, y)=-\frac{2 y}{2-2 x-y}  \tag{2.6}\\
g(x, y, z)=\frac{y^{2}-4(2-2 x-y) z}{(2-2 x-y)^{2}} . \tag{2.7}
\end{gather*}
$$

The proof will be based on the following fact, which is suggested by putting $x=t / n$, $y=Y / n$ and $z=Z / n$ in the results above. For any time $t$, as long as the "remaining time", $n-t$, tends to $\infty$ as $n \rightarrow \infty$, the random variables $Y_{t}$ and $Z_{t}$ can be well approximated by $n y(t / n)$ and $n z(t / n)$ (see Theorem 4), where $y=y(x)$ and $z=z(x)(0 \leq x<1)$ are the solutions of the following differential equations:

$$
\begin{array}{ll}
\frac{d y}{d x}=f(x, y), & y(0)=1 \\
\frac{d z}{d x}=g(x, y, z), & z(0)=0 \tag{2.9}
\end{array}
$$

Thus, by (2.2), $U_{t}$ will be approximated by $n u(t / n)$, where we define

$$
\begin{equation*}
u(x)=2-2 x-y(x) . \tag{2.10}
\end{equation*}
$$

Equation (2.8) and its analogue for a $d$-process in general was used heavily in [5] and [6], where some consequential properties of $y$ were noted. We give these here, as well as similar properties of $z$.

Solving (2.8), by noting that $d x / d y$ is linear in $x$ for example, yields

$$
\begin{equation*}
y(2-\log y)=2(1-x) \tag{2.11}
\end{equation*}
$$

and thus

$$
\begin{equation*}
u=y(1-\log y) \tag{2.12}
\end{equation*}
$$

From this and (2.8) and (2.9) we have

$$
\frac{d z}{d y}=-\frac{1}{2(1-\log y)}+\frac{2 z}{y}
$$

Using the initial condition $z(0)=0$, we then obtain

$$
\begin{equation*}
z(x)=\frac{y(x)^{2}}{2} \int_{y(x)}^{1} \frac{d \eta}{\eta^{2}(1-\log \eta)} \tag{2.13}
\end{equation*}
$$

For our later use we need the following approximations. Note that (2.11) (or (2.8)) implies

$$
\begin{equation*}
0 \leq y(x) \leq 1-x \tag{2.14}
\end{equation*}
$$

Thus, $f(x, y) \leq 0$ and so $y(x)$ is decreasing with $x$. From (2.14) and using the logarithmic inequality $(\log (1-\alpha) \leq-\alpha$ for $\alpha<1)$ twice we get

$$
\begin{align*}
z(x) & \leq \frac{y(x)^{2}}{2} \int_{y(x)}^{1} \frac{d \eta}{\eta^{2}(2-\eta)} \\
& \leq \frac{y(x)(1-y(x))}{2}  \tag{2.15}\\
& \leq \frac{1-x}{2} \tag{2.16}
\end{align*}
$$

Moreover, from (2.11) one can see that

$$
\begin{equation*}
y(x) \sim-2(1-x) / \log (1-x) \quad \text { as } \quad x \rightarrow 1 \tag{2.17}
\end{equation*}
$$

(see also [6, (2.10)]).
The object of this section is to show that the approximations of the random variables $Y$ and $Z$ by the corresponding functions $y$ and $z$ are sufficiently accurate. The proof of Theorem 1 is the most delicate, and for this the process is divided into two phases. For proving the other theorems, the treatment of the second phase could be made much simpler, though we obtain a smaller error in the result of Theorem 2 by careful consideration of Phase 2.

The two phases are $\left[0, t_{1}\right]$ and $\left(t_{1}, n-2\right]$, where we set

$$
\begin{equation*}
t_{1}=n-\left\lceil(\log n)^{N}\right\rceil \tag{2.18}
\end{equation*}
$$

for a large constant $N$ which we specify below. We will be able to estimate $\mathbf{P}\left(\mathcal{C}_{t} \mid G_{t}\right)$ to sufficient accuracy by the non-random value $\bar{r}(x) / n$, where

$$
\bar{r}(x)=\left\{\begin{array}{cl}
r(x), & x \in\left[0, t_{1} / n\right] \\
\frac{1}{2-2 x-n^{-1}}, & x \in\left(t_{1} / n, 1\right]
\end{array}\right.
$$

with

$$
\begin{equation*}
r(x)=\frac{u(x)-y(x)-2 z(x)}{u(x)^{2}} . \tag{2.19}
\end{equation*}
$$

Note that for $t>t_{1}$, we arrive at this approximation by setting $Y_{t}$ and $Z_{t}$ equal to 0 in (2.4), using (2.2). Since $u(x) \geq 1-x$ by (2.10) and (2.14), and since $y(x) \geq 0$ and $z(x) \geq 0$ (see (2.14) and (2.13) respectively), for any $x \in[0,1)$ we have

$$
\begin{equation*}
r(x) \leq \frac{1}{u(x)} \leq \frac{1}{1-x} . \tag{2.20}
\end{equation*}
$$

The following result will play a key role in our proof of Theorems 1, 2 and 3. It is of interest for its own sake since it might be useful in proving some other results concerning the random 2-process. It is in more generality than what is needed in this paper: we will use its special case where $\sigma(n)=t_{1}$ in the proof of Theorems 1-3. Note that it is an improvement of [6, Theorem 2]: the approximation is more accurate and lasts longer, reaching any point such that the remaining time tends to infinity as $n \rightarrow \infty$. Unfortunately, the accuracy of this theorem by itself is not good enough for our purposes in Phase 2, but it is sufficient for Phase 1.

Theorem 4 For any $0<\varepsilon<1 / 4$ and any function $\sigma(n)>0$ with $n-\sigma(n)$ tending to $\infty$ as $n \rightarrow \infty$, there exists $C_{0}=C_{0}(\varepsilon)$, which is independent of $\sigma(n)$, such that with probability $1-O\left(e^{-(n-\sigma(n))^{1 / 2-2 \varepsilon}}\right)$ we have

$$
\begin{align*}
& \left|Y_{t}-n y(t / n)\right|<C_{0}(n-t)^{1-\varepsilon}  \tag{2.21}\\
& \left|Z_{t}-n z(t / n)\right|<C_{0}(n-t)^{1-\varepsilon} \tag{2.22}
\end{align*}
$$

for all $0 \leq t \leq \sigma(n)$, where $y(x)$ and $z(x)$ are determined by (2.11) and (2.13), respectively.

By (2.2), (2.10) and (2.21), under the same conditions as in Theorem 4, we have

$$
\begin{equation*}
\left|U_{t}-n u(t / n)\right|<C_{0}(n-t)^{1-\varepsilon} \tag{2.23}
\end{equation*}
$$

with probability $1-O\left(e^{-(n-\sigma(n))^{1 / 2-2 \varepsilon}}\right)$.
We now specify the values of a set of parameters beginning with any fixed $\rho$ and $K$ with $0<\rho<1$ and $K>4$, as follows. Set $\varepsilon=3 \rho / 16$ and $\zeta=1 / 2-2 \varepsilon=1 / 2-3 \rho / 8$, so that $\zeta>1 / 8$. For the definition (2.18) of $t_{1}$, select $N$ such that $\max \{16 / 3, K / 4 \zeta\}<N<2 K$ so that in particular $\left(n-t_{1}\right)^{\zeta}>(\log n)^{K / 4}$.

In order to introduce the next theorem we note that for large $n$ (using (2.15), (2.11) and $(2.14)), C_{0} /\left(n-t_{1}\right)^{\varepsilon} \leq C_{0} /(\log n)^{N \varepsilon}<1 / 4(\log n)^{16 \varepsilon / 3}=1 / 4(\log n)^{\rho}$, and $n\left(y\left(t_{1} / n\right)+\right.$ $\left.z\left(t_{1} / n\right)\right) /\left(n-t_{1}\right)<2 n y\left(t_{1} / n\right) /\left(n-t_{1}\right)=4 /\left(2-\log y\left(t_{1} / n\right)\right) \leq 4 /\left(2-\log \left(1-t_{1} / n\right)\right)<$ $8 / \log n<1 / 2(\log n)^{\rho}$. Hence with $\sigma=t_{1}$ in Theorem 4,

$$
\begin{equation*}
\mathbf{P}\left(Y_{t_{1}}+Z_{t_{1}}<\frac{n-t_{1}}{(\log n)^{\rho}}\right)=1-O\left(e^{-(\log n)^{K / 4}}\right)=1-o\left(n^{-2}\right) \tag{2.24}
\end{equation*}
$$

To cover the major part of phase 2 we first need to restrict to $t \leq t_{2}$ where

$$
t_{2}=n-\lceil\log n\rceil .
$$

For any graph $G$, denote by $Y(G)$ and $Z(G)$ the numbers of isolated vertices and isolated edges of $G$, respectively.

Theorem 5 Let $0<\rho<1$ and $\mathcal{G}_{1}$ be any set of graphs such that for all $G \in \mathcal{G}_{1}$, $\mathbf{P}\left(G=G_{t_{1}}\right) \neq 0$ and $Y(G)+Z(G)<\left(n-t_{1}\right) /(\log n)^{\rho}$. Then for all $K>0$

$$
\begin{equation*}
\mathbf{P}\left(Y_{t}+Z_{t} \leq \frac{2(n-t)}{(\log n)^{\rho}} \text { for all } t \text { with } t_{1}<t \leq t_{2} \mid G_{t_{1}} \in \mathcal{G}_{1}\right)=1-O\left((\log n)^{-K}\right) \tag{2.25}
\end{equation*}
$$

For the part of phase 2 from $t_{2}$ onwards, we only need some quite simple observations. Lemma 3.1 of [5] was applied to the final stages of the process to show that the random 2-process a.a.s. has a final graph with $Y_{n}+Z_{n}=0$. We need to sharpen this conclusion slightly here. For this purpose we choose $\delta, \delta^{\prime}$ such that

$$
\begin{equation*}
0<\delta^{\prime}<\delta<1, \quad 2\left(1-\rho+\delta^{\prime}\right)<\delta<\frac{1}{2}-\delta^{\prime}<\rho-\frac{1}{2} \tag{2.26}
\end{equation*}
$$

(For example, choosing $\rho=999 / 1000, \delta=2 / 5$ and $\delta^{\prime}=99 / 1000$ satisfies all conditions above.) Let

$$
t_{3}=n-\left\lfloor(\log n)^{\delta}\right\rfloor, \quad t_{4}=n-\left\lfloor(\log n)^{\delta^{\prime}}\right\rfloor .
$$

Theorem 6 Let $0<\rho<1$ and let $\mathcal{G}_{2}$ be any set of graphs such that for all $G \in \mathcal{G}_{2}$, $\mathbf{P}\left(G=G_{t_{2}}\right) \neq 0$ and $Y(G)+Z(G)=O\left((\log n)^{1-\rho}\right)$. Then in the event that $G_{t_{2}} \in \mathcal{G}_{2}$, we have

$$
\begin{equation*}
Y_{t}+Z_{t}=O\left((\log n)^{1-\rho}\right) \text { for } t_{2} \leq t \leq n \tag{2.27}
\end{equation*}
$$

Furthermore,

$$
\begin{equation*}
\mathbf{P}\left(Y_{t_{3}}=0 \mid G_{t_{2}} \in \mathcal{G}_{2}\right)=1-O\left((\log n)^{\delta-\rho}\right) \tag{2.28}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbf{P}\left(Z_{t_{4}}=0 \mid Y_{t_{3}}=0 \wedge G_{t_{2}} \in \mathcal{G}_{2}\right)=1-O\left((\log n)^{\delta^{\prime}-\delta+1-\rho}\right) \tag{2.29}
\end{equation*}
$$

The following result will be useful in computing both the probability of hamiltonicity and the expected number of cycles in the random 2-process.

Lemma 1 For any $t_{0}=t_{0}(n)>0$ such that $n-t_{0}=O(\sqrt{n})$ and $n-t_{0} \rightarrow \infty$ as $n \rightarrow \infty$, we have

$$
\sum_{t=0}^{t_{0}} \frac{1}{n} r\left(\frac{t}{n}\right)=-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)-\frac{\tau}{2}+O\left(\left(n-t_{0}\right)^{-1}+(\log n)^{-1}\right)
$$

Proof Let $r_{1}(x)=(u(x)-y(x)) / u(x)^{2}$ and $r_{2}(x)=-2 z(x) / u(x)^{2}$, so that $r(x)=$ $r_{1}(x)+r_{2}(x)$. Set $J_{1}(t)=\int_{0}^{t / n} r_{1}(x) d x$ and $J_{2}(t)=\int_{0}^{t / n} r_{2}(x) d x$. Using (2.12) we see that $d r_{1} / d y<0$. Since $d y / d x=f(x, y)<0$, it follows that $d r_{1} / d x>0$. Hence

$$
\begin{equation*}
\sum_{t=0}^{t_{0}} r_{1}(t / n) / n=J_{1}\left(t_{0}\right)+O\left(r_{1}\left(t_{0} / n\right) / n\right)=J_{1}\left(t_{0}\right)+O\left(\left(n-t_{0}\right)^{-1}\right) \tag{2.30}
\end{equation*}
$$

(Here we used $r_{1}(x)=-\log y(x) / y(x)(1-\log y(x))^{2} \sim 1 / y(x)(1-\log y(x))=1 /(2(1-$ $x)-y(x)) \sim 1 / 2(1-x)$ as $x \rightarrow 1$, which follows from (2.12), (2.11) and the fact that
$y(x) \rightarrow 0$ when $x \rightarrow 1$.) From (2.11), we have $\log (1-x)=\log y+\log (1-(\log y) / 2)$. Using this and (2.8), and noting $y(0)=1$, we have

$$
\begin{align*}
J_{1}(t) & =\frac{1}{2} \int_{1}^{y(t / n)} \frac{\log y}{y(1-\log y)} d y \\
& =-\frac{1}{2} \log y(t / n)-\frac{1}{2} \log (1-\log y(t / n)) \\
& =-\frac{1}{2} \log y(t / n)-\frac{1}{2} \log (1-(\log y(t / n)) / 2)-\frac{1}{2} \log \left(\frac{1-\log y(t / n)}{1-(\log y(t / n)) / 2}\right) \\
& =-\frac{1}{2} \log (1-t / n)-\frac{1}{2} \log \left(\frac{1-\log y(t / n)}{1-(\log y(t / n)) / 2}\right) . \tag{2.31}
\end{align*}
$$

Since $t_{0} / n \rightarrow 1$, from (2.17) we have $y\left(t_{0} / n\right) \rightarrow 0$ as $n \rightarrow \infty$. Hence, using (2.11) and (2.17), we have

$$
\begin{align*}
J_{1}\left(t_{0}\right) & =-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)-\frac{1}{2} \log \left(\frac{1-\log y\left(t_{0} / n\right)}{2-\log y\left(t_{0} / n\right)}\right) \\
& =-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)+O\left(\frac{1}{2-\log y\left(t_{0} / n\right)}\right) \\
& =-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)+O\left(\frac{y\left(t_{0} / n\right)}{2\left(1-t_{0} / n\right)}\right) \\
& =-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)+O\left(-1 / \log \left(1-t_{0} / n\right)\right) \\
& =-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)+O\left((\log n)^{-1}\right) . \tag{2.32}
\end{align*}
$$

Using (2.8) and (2.13), we get

$$
\begin{align*}
J_{2}(t) & =\int_{1}^{y(t / n)} \frac{z / y}{y(1-\log y)} d y  \tag{2.33}\\
& =\frac{1}{2} \int_{1}^{y(t / n)} \frac{1}{1-\log y} \int_{y}^{1} \frac{1}{\eta^{2}(1-\log \eta)} d \eta d y
\end{align*}
$$

This double integral can be evaluated as follows, first substituting $\xi=1-\log \eta$, then $w=1-\log y, a=w-\xi$ and then reversing the order of integration.

$$
\begin{align*}
J_{2}(t) & =\frac{1}{2} \int_{1-\log y(t / n)}^{1} \int_{1}^{w} \frac{e^{\xi-w}}{\xi w} d \xi d w \\
& =\frac{1}{2} \int_{1-\log y(t / n)}^{1} \int_{0}^{w-1} \frac{e^{-a}}{w(w-a)} d a d w \\
& =\frac{1}{2} \int_{-\log y(t / n)}^{0} e^{-a} \int_{1+a}^{1-\log y(t / n)} \frac{1}{w(w-a)} d w d a \\
& =\frac{1}{2} \int_{-\log y(t / n)}^{0} \frac{1}{a e^{a}} \log \left(\frac{(1-a-\log y(t / n))(1+a)}{1-\log y(t / n)}\right) d a \tag{2.34}
\end{align*}
$$

Since $y\left(t_{0} / n\right) \rightarrow 0$ as $n \rightarrow \infty$, we have

$$
\begin{align*}
J_{2}\left(t_{0}\right)= & -\frac{\tau}{2}-\frac{1}{2} \int_{0}^{-\log y\left(t_{0} / n\right)} \frac{1}{a e^{a}} \log \left(1-\frac{a}{\left.1-\log y\left(t_{0} / n\right)\right)}\right) d a \\
& +\frac{1}{2} \int_{-\log y\left(t_{0} / n\right)}^{\infty} \frac{\log (1+a)}{a e^{a}} d a \\
= & -\frac{\tau}{2}+O\left(-1 / \log \left(1-t_{0} / n\right)\right)+O\left(\int_{-\log y\left(t_{0} / n\right)}^{\infty} e^{-a} d a\right) \\
= & -\frac{\tau}{2}+O\left(-1 / \log \left(1-t_{0} / n\right)\right)+O\left(y\left(t_{0} / n\right)\right) \\
= & -\frac{\tau}{2}+O\left((\log n)^{-1}\right) . \tag{2.35}
\end{align*}
$$

Here the approximation of the first integral is obtained by using (2.11), (2.17) and the logarithmic inequality. The approximation of the second integral is obtained by using $\log (1+a) \leq a$ and then (2.17).

Note that $r_{2}(0)=0$ and $\left|r_{2}\left(t_{0} / n\right)\right| \leq 2 n /\left(n-t_{0}\right)$ since $z(0)=0, z\left(t_{0} / n\right) \leq\left(1-t_{0} / n\right) / 2$ and $u\left(t_{0} / n\right) \geq 1-t_{0} / n$. Thus, using the Trapezoidal Rule and its error bound from numerical integration, we have

$$
\begin{align*}
\sum_{t=0}^{t_{0}} r_{2}(t / n) / n & =J_{2}\left(t_{0}\right)+\left(r_{2}(0)+r_{2}\left(t_{0} / n\right)\right) / 2 n+O\left(n^{-2}\right) \\
& =J_{2}\left(t_{0}\right)+O\left(\left(n-t_{0}\right)^{-1}\right) \tag{2.36}
\end{align*}
$$

Therefore, combining (2.30) and (2.36), and using (2.32) and (2.35), we obtain

$$
\begin{aligned}
\sum_{t=0}^{t_{0}} r(t / n) / n & =\sum_{t=0}^{t_{0}} r_{1}(t / n) / n+\sum_{t=0}^{t_{0}} r_{2}(t / n) / n \\
& =-\frac{1}{2} \log \left(2\left(n-t_{0}\right) / n\right)-\frac{\tau}{2}+O\left(\left(n-t_{0}\right)^{-1}+(\log n)^{-1}\right)
\end{aligned}
$$

and the proof is complete.
Proof of Theorem 1 Define $\mathcal{H}_{t}$ to be the event that $G_{t}$ contains no cycles, which is just $\left(\bigwedge_{i=0}^{t-1} \overline{\mathcal{C}}_{i}\right)$. Set $t_{5}=n-1$. For $t \leq t_{1}$ define $\mathcal{E}_{t}$ to be the event that $Y_{t}$ and $Z_{t}$ satisfy the inequalities (2.21) and (2.22). For $t_{1}<t \leq t_{2}$ let $\mathcal{E}_{t}$ be the event that $Y_{t}+Z_{t} \leq 2(n-t) /(\log n)^{\rho}$. Let $\mathcal{E}_{t_{3}}$ be the event that $Y_{t_{3}}=0$ and $Z_{t_{3}}<(\log n)^{1-\rho}$, and $\mathcal{E}_{t_{4}}$ the event that $Y_{t_{4}}=Z_{t_{4}}=0$. We define $\mathcal{F}_{t_{i}}$ to be an event that ensures that no cycles have been created, and that $Y_{t}$ and $Z_{t}$ satisfy appropriate inequalities, for all $t \leq t_{i}$. To be precise, we let $\mathcal{F}_{t_{i}}=\mathcal{H}_{t_{i}} \wedge \mathcal{E}_{t_{1}} \wedge \cdots \wedge \mathcal{E}_{t_{i}}$ for $1 \leq i \leq 4$, and $\mathcal{F}_{t_{5}}=\mathcal{F}_{t_{4}} \wedge \mathcal{H}_{t_{5}}$. Then $\mathcal{F}_{t_{i}}=\mathcal{F}_{t_{i-1}} \wedge \mathcal{H}_{t_{i}} \wedge \mathcal{E}_{t_{i}}$ for $i=2,3,4$, and

$$
\mathcal{H}_{t_{5}}=\left(\mathcal{H}_{t_{5}} \wedge \overline{\mathcal{F}}_{t_{4}}\right) \vee\left(\mathcal{H}_{t_{5}} \wedge \mathcal{F}_{t_{4}}\right)=\left(\mathcal{H}_{t_{5}} \wedge \overline{\mathcal{F}}_{t_{4}}\right) \vee \mathcal{F}_{t_{5}} .
$$

Noting that $\mathcal{H}_{t_{5}} \wedge \overline{\mathcal{H}}_{t_{4}}=\emptyset$, we have

$$
\mathcal{H}_{t_{5}} \wedge \overline{\mathcal{F}}_{t_{4}}=\bigvee_{i=1}^{4}\left(\mathcal{H}_{t_{5}} \wedge \overline{\mathcal{E}}_{t_{i}}\right) \subseteq \overline{\mathcal{E}}_{t_{1}} \vee\left(\bigvee_{i=1}^{3}\left(\mathcal{H}_{t_{i}} \wedge \overline{\mathcal{E}}_{t_{i+1}}\right)\right) \subseteq \overline{\mathcal{E}}_{t_{1}} \vee\left(\bigvee_{i=1}^{3}\left(\mathcal{F}_{t_{i}} \wedge \overline{\mathcal{E}}_{t_{i+1}}\right)\right)
$$

and so

$$
\mathcal{F}_{t_{5}} \subseteq \mathcal{H}_{t_{5}} \subseteq \overline{\mathcal{E}}_{t_{1}} \vee\left(\bigvee_{i=1}^{3}\left(\mathcal{F}_{t_{i}} \wedge \overline{\mathcal{E}}_{t_{i+1}}\right)\right) \vee \mathcal{F}_{t_{5}}
$$

Hence by (2.1)

$$
\begin{equation*}
\mathbf{P}\left(G_{n} \text { is hamiltonian }\right)=\mathbf{P}\left(\mathcal{F}_{t_{5}}\right)+O\left(\mathbf{P}\left(\overline{\mathcal{E}}_{t_{1}}\right)+\sum_{i=1}^{3} \mathbf{P}\left(\mathcal{F}_{t_{i}} \wedge \overline{\mathcal{E}}_{t_{i+1}}\right)\right) \tag{2.37}
\end{equation*}
$$

Since the $\mathcal{F}_{t_{i}}$ are nested, the main term $\mathbf{P}\left(\mathcal{F}_{t_{5}}\right)$ in this equation can be computed using

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{F}_{t_{5}}\right)=\mathbf{P}\left(\mathcal{F}_{t_{1}}\right) \prod_{i=1}^{4} \mathbf{P}\left(\mathcal{F}_{t_{i+1}} \mid \mathcal{F}_{t_{i}}\right) . \tag{2.38}
\end{equation*}
$$

In the following we will estimate the factors in this expression one by one.
Since $\mathcal{F}_{t_{1}}=\mathcal{H}_{t_{1}} \wedge \mathcal{E}_{t_{1}}$, the first factor in (2.38) is

$$
\begin{align*}
\mathbf{P}\left(\mathcal{F}_{t_{1}}\right) & =\mathbf{P}\left(\mathcal{H}_{t_{1}}\right)-\mathbf{P}\left(\mathcal{H}_{t_{1}} \wedge \overline{\mathcal{E}}_{t_{1}}\right) \\
& =\mathbf{P}\left(\mathcal{H}_{t_{1}}\right)+O\left(\mathbf{P}\left(\overline{\mathcal{E}}_{t_{1}}\right)\right) . \tag{2.39}
\end{align*}
$$

Similar to (2.1), since $\mathbf{P}\left(\mathcal{H}_{0}\right)=1$,

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{H}_{t}\right)=\mathbf{P}\left(\bigwedge_{i=0}^{t-1} \overline{\mathcal{C}}_{i}\right)=\prod_{i=0}^{t-1} \mathbf{P}\left(\overline{\mathcal{C}}_{i} \mid \mathcal{H}_{i}\right) . \tag{2.40}
\end{equation*}
$$

From (2.2) and (2.4), $\mathbf{P}\left(\mathcal{C}_{i} \mid G_{i}\right)$ is maximised for given $i$ when $Y_{i}=Z_{i}=0$, that is

$$
\mathbf{P}\left(\mathcal{C}_{i} \mid G_{i}\right) \leq \frac{1}{2 n-2 i-1}
$$

We therefore have the initial bound

$$
\mathbf{P}\left(\mathcal{H}_{t}\right) \geq \prod_{i=0}^{t-1}\left(1-\frac{1}{2 n-2 i-1}\right)=\prod_{j=n-t}^{n-1} \frac{2 j}{2 j+1} .
$$

We note for here and later that

$$
\begin{equation*}
\prod_{j=1}^{s-2} \frac{2 j}{2 j+1}=\frac{2^{2 s-3}(s-2)!(s-1)!}{(2 s-2)!} \sim \frac{1}{2}\left(\frac{\pi}{s}\right)^{1 / 2} \tag{2.41}
\end{equation*}
$$

where the last estimate is by Stirling's formula. Thus, for all $t \leq n-1$,

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{H}_{t}\right)=\Omega\left(\left(\frac{n-t}{n}\right)^{1 / 2}\right) \tag{2.42}
\end{equation*}
$$

For $t<t_{1}$, since $\mathcal{E}_{t}$ implies (2.21) and (2.22), we have

$$
\begin{align*}
\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{E}_{t}\right) & =\frac{U_{t}-Y_{t}-2 Z_{t}}{U_{t}^{2}}\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\frac{u(t / n)-y(t / n)-2 z(t / n)+O\left((n-t)^{1-\varepsilon} / n\right)}{n\left(u(t / n)-O\left((n-t)^{1-\varepsilon} / n\right)\right)^{2}}\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\left(\frac{\bar{r}(t / n)}{n}+O\left(\frac{(n-t)^{1-\varepsilon}}{n^{2}(u(t / n))^{2}}\right)\right)\left(1+O\left(\frac{(n-t)^{1-\varepsilon}}{n u(t / n)}\right)\right)\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\left(\frac{\bar{r}(t / n)}{n}+O\left(\frac{(n-t)^{1-\varepsilon}}{n^{2}(u(t / n))^{2}}\right)\right)\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\left(\frac{\bar{r}(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right)\right)\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right) . \tag{2.43}
\end{align*}
$$

Here in the third last step we used $\bar{r}(t / n) \leq 1 / u(t / n)$, which follows from the left part of (2.20). In the second last step we used the right part of (2.20), and in the last step we used $\bar{r}(t / n) / n \leq 1 /(n-t)$ from (2.20) and $U_{t} \geq n-t$ from (2.3). By (2.42) and Theorem 4 with $\sigma(n)=t_{1}$, and noting that $N>K / 4 \zeta$, similar to the argument leading to (2.24) we get $\mathbf{P}\left(\overline{\mathcal{E}}_{t}\right) / \mathbf{P}\left(\mathcal{H}_{t}\right)=O\left(e^{-(\log n)^{K / 4}} \sqrt{n} / \sqrt{n-t}\right)=O\left(n^{-2} \sqrt{n} / \sqrt{n-t}\right)$. Combining this and (2.43), we have for $t<t_{1}$,

$$
\begin{align*}
\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t}\right) & \leq \mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{E}_{t}\right)+\mathbf{P}\left(\mathcal{C}_{t} \wedge \overline{\mathcal{E}}_{t} \mid \mathcal{H}_{t}\right) \\
& \leq \mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{E}_{t}\right)+\mathbf{P}\left(\overline{\mathcal{E}}_{t}\right) / \mathbf{P}\left(\mathcal{H}_{t}\right) \\
& =\frac{\bar{r}(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right)+O\left(n^{-3 / 2}\right)  \tag{2.44}\\
& =\frac{\bar{r}(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right) . \tag{2.45}
\end{align*}
$$

Here the last step follows from the fact that $\varepsilon=3 \rho / 16<1 / 4$. From (2.40) and (2.45), we have, for any $t \leq t_{1}$,

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{H}_{t}\right)=\prod_{i=0}^{t-1}\left(1-\frac{1}{n} r\left(\frac{i}{n}\right)+O\left((n-i)^{-1-\varepsilon}\right)\right) \sim \exp \left(-\sum_{i=0}^{t-1} \frac{1}{n} r\left(\frac{i}{n}\right)\right) . \tag{2.46}
\end{equation*}
$$

Applying this to time $t=t_{1}$ and noting that $\mathbf{P}\left(\overline{\mathcal{E}}_{t_{1}}\right)=o\left(n^{-2}\right)$ by Theorem 4, from (2.39) we have

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{F}_{t_{1}}\right) \sim \exp \left(-\sum_{t=0}^{t_{1}-1} \frac{1}{n} r\left(\frac{t}{n}\right)\right) \sim\left(\frac{2\left(n-t_{1}\right) e^{\tau}}{n}\right)^{1 / 2} \tag{2.47}
\end{equation*}
$$

where the last estimate is from Lemma 1.
We may treat the factor due to $i$ in (2.38) using a similar argument, from (2.40) onwards, conditioning on $\mathcal{F}_{t_{i}}$. This argument is entirely restricted to the time period from $t_{i}$ to $t_{i+1}$. In fact, similar to (2.39) and (2.42), for $i=1,2,3$ we have

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{F}_{t_{i+1}} \mid \mathcal{F}_{t_{i}}\right)=\mathbf{P}\left(\mathcal{H}_{t_{i+1}} \mid \mathcal{F}_{t_{i}}\right)+O\left(\mathbf{P}\left(\overline{\mathcal{E}}_{t_{i+1}} \mid \mathcal{F}_{t_{i}}\right)\right) \tag{2.48}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{H}_{t} \mid \mathcal{F}_{t_{i}}\right)=\Omega\left(\left(\frac{n-t}{n-t_{i}}\right)^{1 / 2}\right) \tag{2.49}
\end{equation*}
$$

for $t_{i}<t \leq n-1$. For $i=1$ and $t_{1}<t \leq t_{2}$, we have $\bar{r}(t / n) / n=1 /(2(n-t)-1)$, $U_{t} \geq n-t \geq n-t_{2} \geq \log n>(\log n)^{\rho}$ and $\mathcal{E}_{t}$ implies $Y_{t}+Z_{t} \leq 2(n-t) /(\log n)^{\rho}$. Thus, similar to (2.43), we have

$$
\begin{align*}
\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{E}_{t} \wedge \mathcal{F}_{t_{1}}\right) & =\frac{\bar{r}(t / n)}{n}\left(1-\frac{Y_{t}+2 Z_{t}}{2(n-t)-Y_{t}}\right) \frac{2(n-t)-1}{2(n-t)-Y_{t}}\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}\left(1-O\left(\frac{Y_{t}+Z_{t}}{n-t}\right)\right)\left(1+O\left(\frac{Y_{t}}{n-t}\right)\right)\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho}\right)\right)\left(1+O\left(\frac{1}{U_{t}}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}+O\left((\log n)^{-1-\rho}\right) . \tag{2.50}
\end{align*}
$$

Since $\mathcal{F}_{t_{1}}$ implies $\mathcal{E}_{t_{1}}$, we have $Y_{t_{1}}+Z_{t_{1}}<\left(n-t_{1}\right) /(\log n)^{\rho}$. Thus, by an argument similar to that leading to (2.24), we get $\mathbf{P}\left(\overline{\mathcal{E}}_{t} \mid \mathcal{F}_{t_{1}}\right)=O\left((\log n)^{-K}\right)$ for all $t$ with $t_{1}<t \leq t_{2}$ by Theorem 5. From (2.49) we then have

$$
\mathbf{P}\left(\overline{\mathcal{E}}_{t} \mid \mathcal{F}_{t_{1}}\right) / \mathbf{P}\left(\mathcal{H}_{t} \mid \mathcal{F}_{t_{1}}\right)=O\left((\log n)^{-K}\left(\left(n-t_{1}\right) /\left(n-t_{2}\right)\right)^{1 / 2}\right)=O\left((\log n)^{-K+(N-1) / 2}\right) .
$$

From this and (2.50), using an argument similar to that leading to (2.45), we obtain

$$
\begin{aligned}
\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{1}}\right) & =\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{E}_{t} \wedge \mathcal{F}_{t_{1}}\right)+O\left(\mathbf{P}\left(\overline{\mathcal{E}}_{t} \mid \mathcal{F}_{t_{1}}\right) / \mathbf{P}\left(\mathcal{H}_{t} \mid \mathcal{F}_{t_{1}}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}+O\left((\log n)^{-1-\rho}\right)+O\left((\log n)^{-K+(N-1) / 2}\right)
\end{aligned}
$$

It follows that the first term of (2.48) when $i=1$ is

$$
\mathbf{P}\left(\mathcal{H}_{t_{2}} \mid \mathcal{F}_{t_{1}}\right)=\prod_{t=t_{1}}^{t_{2}-1} \mathbf{P}\left(\overline{\mathcal{C}}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{1}}\right) \sim \prod_{t=t_{1}}^{t_{2}-1}\left(1-\frac{\bar{r}(t / n)}{n}\right)
$$

which is $\prod_{t=t_{1}}^{t_{2}-1}(2(n-t)-2) /(2(n-t)-1)=\Omega\left((\log n)^{-(N-1) / 2}\right)$ by (2.41). By Theorem 5 , the second term $O\left(\mathbf{P}\left(\overline{\mathcal{E}}_{t_{2}} \mid \mathcal{F}_{t_{1}}\right)\right)$ of $(2.48)$ when $i=1$ is $O\left((\log n)^{-K}\right)$, which is $o\left((\log n)^{-(N-1) / 2}\right)$ since $N<2 K+1$. From (2.48) we then obtain

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{F}_{t_{2}} \mid \mathcal{F}_{t_{1}}\right) \sim \prod_{t=t_{1}}^{t_{2}-1}\left(1-\frac{\bar{r}(t / n)}{n}\right) . \tag{2.51}
\end{equation*}
$$

For the factor due to $i=2$ in (2.38), we condition on $\mathcal{F}_{t_{2}}$ and consider the time period from $t_{2}$ to $t_{3}$. Note that $\mathcal{F}_{t_{2}}$ implies $Y_{t_{2}}+Z_{t_{2}} \leq 2\left(n-t_{2}\right) /(\log n)^{\rho}=2(\log n)^{1-\rho}$ and hence
$Y_{t}+Z_{t}=O\left((\log n)^{1-\rho}\right)$ for $t_{2} \leq t<t_{3}$, since $Y_{t}+Z_{t}$ is non-increasing with $t$ (see (3.3)). Note also that $U_{t} \geq n-t \geq n-t_{3}>(\log n)^{-1+\rho+\delta}$ for $t_{2} \leq t<t_{3}$ since $\rho<1$ and $n-t_{3}=\left\lfloor(\log n)^{\delta}\right\rfloor$. Thus, similar to (2.50), we have

$$
\begin{align*}
\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{2}}\right) & =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho-\delta+1}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}+O\left((\log n)^{-\rho-2 \delta+1}\right) \tag{2.52}
\end{align*}
$$

for $t_{2} \leq t<t_{3}$. Consequently,

$$
\mathbf{P}\left(\mathcal{H}_{t_{3}} \mid \mathcal{F}_{t_{2}}\right)=\prod_{t=t_{2}}^{t_{3}-1} \mathbf{P}\left(\overline{\mathcal{C}}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{2}}\right) \sim \prod_{t=t_{2}}^{t_{3}-1}\left(1-\frac{\bar{r}(t / n)}{n}\right)
$$

which is $\prod_{t=t_{2}}^{t_{3}-1}(2(n-t)-2) /(2(n-t)-1)=\Omega\left((\log n)^{-(1-\delta) / 2}\right)$ by $(2.41)$. By Theorem 6 the second term of $(2.48)$ when $i=2$ is $O\left((\log n)^{\delta-\rho}\right)$, and hence is $o\left((\log n)^{-(1-\delta) / 2}\right)$ since $\delta<2 \rho-1$ by (2.26). Hence

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{F}_{t_{3}} \mid \mathcal{F}_{t_{2}}\right) \sim \prod_{t=t_{2}}^{t_{3}-1}\left(1-\frac{\bar{r}(t / n)}{n}\right) . \tag{2.53}
\end{equation*}
$$

For the factor due to $i=3$ in (2.38), similar to (2.52), we have

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{C}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{3}}\right)=\frac{\bar{r}(t / n)}{n}+O\left((\log n)^{-\rho-2 \delta^{\prime}+1}\right) \tag{2.54}
\end{equation*}
$$

for $t_{3} \leq t<t_{4}$. Thus,

$$
\mathbf{P}\left(\mathcal{H}_{t_{4}} \mid \mathcal{F}_{t_{3}}\right)=\prod_{t=t_{3}}^{t_{4}-1} \mathbf{P}\left(\overline{\mathcal{C}}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{3}}\right) \sim \prod_{t=t_{3}}^{t_{4}-1}\left(1-\frac{\bar{r}(t / n)}{n}\right)
$$

which is $\prod_{t=t_{3}}^{t_{4}-1}(2(n-t)-2) /(2(n-t)-1)=\Omega\left((\log n)^{-\left(\delta-\delta^{\prime}\right) / 2}\right)$ by $(2.41)$. By Theorem 6 , when $i=3$ the second term of $(2.48)$ is $O\left((\log n)^{-\rho-\left(\delta-\delta^{\prime}\right)+1}\right)$, and hence is $o\left((\log n)^{-\left(\delta-\delta^{\prime}\right) / 2}\right)$ as $\left(\delta-\delta^{\prime}\right) / 2+\rho>1$. Therefore,

$$
\begin{equation*}
\mathbf{P}\left(\mathcal{F}_{t_{4}} \mid \mathcal{F}_{t_{3}}\right) \sim \prod_{t=t_{3}}^{t_{4}-1}\left(1-\frac{\bar{r}(t / n)}{n}\right) \tag{2.55}
\end{equation*}
$$

The factor due to $i=4$ in (2.38) can be computed directly. Conditioning on $\mathcal{F}_{t_{4}}$, we have $Y_{t_{4}}=Z_{t_{4}}=0$ and hence $Y_{t}=Z_{t}=0$ for $t \geq t_{4}$ since $Y_{t}+Z_{t}$ is non-increasing with $t$ (see (3.3)). Thus, as $\mathcal{F}_{t_{5}}=\mathcal{F}_{t_{4}} \wedge \mathcal{H}_{t_{5}}$, from (2.4) we have

$$
\begin{align*}
\mathbf{P}\left(\mathcal{F}_{t_{5}} \mid \mathcal{F}_{t_{4}}\right) & =\mathbf{P}\left(\mathcal{H}_{t_{5}} \mid \mathcal{F}_{t_{4}}\right) \\
& =\prod_{t=t_{4}}^{t_{5}-1} \mathbf{P}\left(\overline{\mathcal{C}}_{t} \mid \mathcal{H}_{t} \wedge \mathcal{F}_{t_{4}}\right) \\
& =\prod_{t=t_{4}}^{n-2}\left(1-\frac{1}{2(n-t)-1}\right) \\
& =\prod_{t=t_{4}}^{n-2}\left(1-\frac{\bar{r}(t / n)}{n}\right) . \tag{2.56}
\end{align*}
$$

Plugging (2.47), (2.51), (2.53), (2.55) and (2.56) into (2.38) and using (2.41) we obtain

$$
\begin{aligned}
\mathbf{P}\left(\mathcal{F}_{t_{5}}\right) & \sim\left(\frac{2\left(n-t_{1}\right) e^{\tau}}{n}\right)^{1 / 2} \prod_{t=t_{1}}^{n-2}\left(1-\frac{\bar{r}(t / n)}{n}\right) \\
& =\left(\frac{2\left(n-t_{1}\right) e^{\tau}}{n}\right)^{1 / 2} \prod_{t=t_{1}}^{n-2} \frac{2(n-t)-2}{2(n-t)-1} \\
& \sim\left(\frac{2\left(n-t_{1}\right) e^{\tau}}{n}\right)^{1 / 2} \frac{1}{2}\left(\frac{\pi}{n-t_{1}}\right)^{1 / 2} \\
& =\sqrt{\frac{\pi e^{\tau}}{2} / \sqrt{n} .}
\end{aligned}
$$

Thus, to complete the proof of Theorem 1, it remains to show that the second term in (2.37) is negligible, that is, it is $o(1 / \sqrt{n})$. In fact, we have $\mathbf{P}\left(\overline{\mathcal{E}}_{t_{1}}\right)=O\left(e^{-\left(n-t_{1}\right)^{\varsigma}}\right)=$ $O\left(e^{-(\log n)^{K / 4}}\right)=o\left(n^{-2}\right)$ by Theorem 4. By Theorem 5 and (2.47), and since $N<2 K$ by our assumption, we have

$$
\begin{aligned}
\mathbf{P}\left(\mathcal{F}_{t_{1}} \wedge \overline{\mathcal{E}}_{t_{2}}\right) & =\mathbf{P}\left(\overline{\mathcal{E}}_{t_{2}} \mid \mathcal{F}_{t_{1}}\right) \mathbf{P}\left(\mathcal{F}_{t_{1}}\right) \\
& =O\left((\log n)^{-K}\left(\frac{n-t_{1}}{n}\right)^{1 / 2}\right) \\
& =O\left((\log n)^{-K+N / 2} / \sqrt{n}\right) \\
& =o(1 / \sqrt{n})
\end{aligned}
$$

Similarly, by Theorem $6,(2.47)$ and (2.51), and noting that $\delta<\rho-1 / 2$ by (2.26),

$$
\begin{aligned}
\mathbf{P}\left(\mathcal{F}_{t_{2}} \wedge \overline{\mathcal{E}}_{t_{3}}\right) & =\mathbf{P}\left(\overline{\mathcal{E}}_{t_{3}} \mid \mathcal{F}_{t_{2}}\right) \mathbf{P}\left(\mathcal{F}_{t_{2}} \mid \mathcal{F}_{t_{1}}\right) \mathbf{P}\left(\mathcal{F}_{t_{1}}\right) \\
& =O\left((\log n)^{\delta-\rho+(1-N) / 2+N / 2} / \sqrt{n}\right) \\
& =o(1 / \sqrt{n})
\end{aligned}
$$

Again, by Theorem $6,(2.47),(2.51)$ and (2.53), and using $\delta / 2-\delta^{\prime}+\rho>1$ from (2.26), we have

$$
\begin{aligned}
\mathbf{P}\left(\mathcal{F}_{t_{3}} \wedge \overline{\mathcal{E}}_{t_{4}}\right) & =\mathbf{P}\left(\overline{\mathcal{E}}_{t_{4}} \mid \mathcal{F}_{t_{3}}\right) \mathbf{P}\left(\mathcal{F}_{t_{3}} \mid \mathcal{F}_{t_{2}}\right) \mathbf{P}\left(\mathcal{F}_{t_{2}} \mid \mathcal{F}_{t_{1}}\right) \mathbf{P}\left(\mathcal{F}_{t_{1}}\right) \\
& =O\left((\log n)^{\left(\delta^{\prime}-\delta+1-\rho\right)+(\delta-1) / 2+(1-N) / 2+N / 2} / \sqrt{n}\right) \\
& =o(1 / \sqrt{n}) .
\end{aligned}
$$

The proof of Theorem 1 is complete.
The approximation results and the analysis in the proof of Theorem 1 contain essentially what we need in order to prove Theorem 2.
Proof of Theorem 2 Denote $Q_{t}=\left(n-t-Y_{t}-Z_{t}\right) /\left(\binom{U_{t}}{2}-Z_{t}\right)$. Then $Q_{t}=O\left((n-t)^{-1}\right)$ for all $t$ and by (2.4) the probability of creating a cycle at time $t$ is equal to $Q_{t}$. Let $\mathcal{E}_{t}$ be
as in the proof of Theorem 1. For $t$ up to $t_{2}$ we will use the following to estimate $\mathbf{E}\left(Q_{t}\right)$ :

$$
\begin{align*}
\mathbf{E}\left(Q_{t}\right) & =\mathbf{E}\left(Q_{t} \mid \mathcal{E}_{t}\right) \mathbf{P}\left(\mathcal{E}_{t}\right)+\mathbf{E}\left(Q_{t} \mid \overline{\mathcal{E}}_{t}\right) \mathbf{P}\left(\overline{\mathcal{E}}_{t}\right) \\
& =\mathbf{E}\left(Q_{t} \mid \mathcal{E}_{t}\right) \mathbf{P}\left(\mathcal{E}_{t}\right)+O\left((n-t)^{-1} \mathbf{P}\left(\overline{\mathcal{E}}_{t}\right)\right) \tag{2.57}
\end{align*}
$$

Taking $\sigma(n)=t_{1}$ in Theorem 4, we have $\mathbf{P}\left(\mathcal{E}_{t}\right)=1-o\left(n^{-2}\right)$ for $t \leq t_{1}$. By using arguments similar to that leading to (2.43), one can show that

$$
\mathbf{E}\left(Q_{t} \mid \mathcal{E}_{t}\right)=\frac{r(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right)
$$

for $t \leq t_{1}$. Thus, by (2.57) and noting that $r(t / n) / n=O\left((n-t)^{-1}\right)$, for $t \leq t_{1}$ we have

$$
\begin{align*}
\mathbf{E}\left(Q_{t}\right) & =\left(\frac{r(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right)\right)\left(1-o\left(n^{-2}\right)\right)+O\left((n-t)^{-1} n^{-2}\right) \\
& =\frac{r(t / n)}{n}+O\left((n-t)^{-1-\varepsilon}\right) \tag{2.58}
\end{align*}
$$

Note that (2.21) and (2.22) imply (2.24), and in particular $Y_{t_{1}}+Z_{t_{1}}<\left(n-t_{1}\right) /(\log n)^{\rho}$ with probability $1-o\left(n^{-2}\right)$. Hence, for $t_{1}<t \leq t_{2}, \mathbf{P}\left(\mathcal{E}_{t}\right)=1-O\left((\log n)^{-K}\right)$ by Theorem 5. Using an argument similar to that leading to (2.50), we get

$$
\mathbf{E}\left(Q_{t} \mid \mathcal{E}_{t}\right)=\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho}\right)\right)
$$

and hence (2.57) gives

$$
\begin{align*}
\mathbf{E}\left(Q_{t}\right) & =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho}\right)\right)\left(1-O\left((\log n)^{-K}\right)\right)+O\left((n-t)^{-1}(\log n)^{-K}\right) \\
& =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho}\right)\right) \tag{2.59}
\end{align*}
$$

for $t_{1}<t \leq t_{2}$.
For $t_{2}<t \leq t_{4}$ we condition on the event $\mathcal{A}_{t}$ that $Y_{t}+Z_{t} \leq C^{*}(\log n)^{1-\rho}$ for a sufficiently large $C^{*}$. Since $\mathbf{P}\left(\mathcal{E}_{t_{2}}\right)=\mathbf{P}\left(Y_{t_{2}}+Z_{t_{2}} \leq 2(\log n)^{1-\rho}\right)=1-O\left((\log n)^{-K}\right)$, from Theorem 6 it follows that $\mathbf{P}\left(\mathcal{A}_{t}\right)=1-O\left((\log n)^{-K}\right)$. Similar to the proof of (2.52), for $t_{2}<t \leq t_{3}$ we have

$$
\mathbf{E}\left(Q_{t} \mid \mathcal{A}_{t}\right)=\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho-\delta+1}\right)\right) .
$$

Based on this and using an expression similar to (2.57) we have

$$
\begin{align*}
\mathbf{E}\left(Q_{t}\right) & =\mathbf{E}\left(Q_{t} \mid \mathcal{A}_{t}\right) \mathbf{P}\left(\mathcal{A}_{t}\right)+O\left((n-t)^{-1} \mathbf{P}\left(\overline{\mathcal{A}}_{t}\right)\right) \\
& =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho-\delta+1}\right)\right)\left(1-O\left((\log n)^{-K}\right)\right)+O\left((n-t)^{-1}(\log n)^{-K}\right) \\
& =\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho-\delta+1}\right)\right) . \tag{2.60}
\end{align*}
$$

In a similar fashion, for $t_{3}<t \leq t_{4}$, we obtain

$$
\begin{equation*}
\mathbf{E}\left(Q_{t}\right)=\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{-\rho-\delta^{\prime}+1}\right)\right) . \tag{2.61}
\end{equation*}
$$

For $t_{4} \leq t<n$, we condition on the event $\mathcal{A}_{t}$ that $Y_{t}=Z_{t}=0$, which holds with probability $1-O\left((\log n)^{\delta^{\prime}-\delta+1-\rho}\right)$ by (2.28) and (2.29). Thus, since $\mathbf{E}\left(Q_{t} \mid \mathcal{A}_{t}\right)=\bar{r}(t / n) / n$, analogous to (2.60) we have

$$
\begin{equation*}
\mathbf{E}\left(Q_{t}\right)=\frac{\bar{r}(t / n)}{n}\left(1+O\left((\log n)^{\delta^{\prime}-\delta+1-\rho}\right)\right) . \tag{2.62}
\end{equation*}
$$

Using (2.58)-(2.62) and noting (2.26), we have

$$
\begin{align*}
\mathbf{E}\left(X_{n}\right) & =\sum_{t=0}^{n-1} \mathbf{P}(\text { a cycle is formed at time } t) \\
& =\sum_{t=0}^{n-1} \mathbf{E}\left(Q_{t}\right) \\
& =\sum_{t=0}^{t_{1}} \frac{r(t / n)}{n}+\left(1+O\left((\log n)^{-\rho-\delta^{\prime}+1}\right)\right) \sum_{t=t_{1}+1}^{n-1} \frac{\bar{r}(t / n)}{n}+O\left(\sum_{t=0}^{t_{1}}(n-t)^{-1-\varepsilon}\right) \\
& =\sum_{t=0}^{t_{1}} \frac{r(t / n)}{n}+\left(1+O\left((\log n)^{-\rho-\delta^{\prime}+1}\right)\right) \sum_{t=t_{1}+1}^{n-1} \frac{\bar{r}(t / n)}{n}+O\left((\log n)^{-N \varepsilon}\right) . \tag{2.63}
\end{align*}
$$

From Lemma 1,

$$
\sum_{t=0}^{t_{1}} \frac{r(t / n)}{n}=-\frac{1}{2} \log \left(2\left(n-t_{1}\right) / n\right)-\frac{\tau}{2}+O\left((\log n)^{-1}\right)
$$

Also, noting that the harmonic number $H(k)=\sum_{j=1}^{k} 1 / k=\log k+\gamma+O(1 / k)$, we have

$$
\begin{aligned}
\sum_{t=t_{1}+1}^{n-1} \frac{\bar{r}(t / n)}{n} & =\sum_{t=1}^{n-t_{1}-1} \frac{1}{2 t-1} \\
& =H\left(2\left(n-t_{1}-1\right)\right)-\frac{1}{2} H\left(n-t_{1}-1\right) \\
& =\log \left(2\left(n-t_{1}\right)\right)+\gamma-\frac{1}{2}\left(\log \left(n-t_{1}\right)+\gamma\right)+O\left(\frac{1}{n-t_{1}}\right) \\
& =\frac{1}{2} \log \left(2\left(n-t_{1}\right)\right)+\frac{1}{2}(\gamma+\log 2)+O\left(\frac{1}{(\log n)^{N}}\right)
\end{aligned}
$$

Plugging the two sums above into (2.63) and noting that $N \varepsilon=N \rho / 4>\rho>\rho+\delta^{\prime}-1$, we obtain $\mathbf{E}\left(X_{n}\right)=\frac{1}{2}(\log n+\log 2+\gamma-\tau)+O\left((\log n)^{-\rho-\delta^{\prime}+1} \log \log n\right)$, where the $\log \log n$ factor is due to $\log \left(n-t_{1}\right)$ by noting (2.18). For the specific choice of $\rho, \delta$ and $\delta^{\prime}$ after (2.26), we have $\rho+\delta^{\prime}>12 / 11$ and hence the error term is $O\left((\log n)^{-1 / 11}\right)$, as required in Theorem 2.

Proof of Theorem 3 We will use the notation in the proof of Theorem 1. Recall that $\mathcal{H}_{t}=\bigwedge_{i=0}^{t-1} \overline{\mathcal{C}}_{i}$ is the event that $G_{t}$ contains no cycles. We have

$$
\begin{align*}
\mathbf{E}\left(T_{n}\right) & =\sum_{t=1}^{n} \mathbf{P}\left(T_{n} \geq t\right) \\
& =\sum_{t=0}^{n-1} \mathbf{P}\left(\mathcal{H}_{t}\right) \\
& =\sum_{t=0}^{t_{1}} \mathbf{P}\left(\mathcal{H}_{t}\right)+\sum_{t=t_{1}+1}^{n-1} \mathbf{P}\left(\mathcal{H}_{t}\right) . \tag{2.64}
\end{align*}
$$

By the definition of $t_{1}$ and the fact that $\mathcal{H}_{t} \subseteq \mathcal{H}_{t-1}$ for any $t$, using (2.46) (for $t=t_{1}$ ) and then Lemma 1 (as in (2.47)) we have

$$
\begin{aligned}
\sum_{t=t_{1}+1}^{n-1} \mathbf{P}\left(\mathcal{H}_{t}\right) & \leq(\log n)^{N} \mathbf{P}\left(\mathcal{H}_{t_{1}}\right) \\
& \sim(\log n)^{N} \exp \left(-\sum_{t=0}^{t_{1}-1} \frac{1}{n} r\left(\frac{t}{n}\right)\right) \\
& \sim(\log n)^{N}\left(\frac{2\left(n-t_{1}\right) e^{\tau}}{n}\right)^{1 / 2} \\
& \sim\left(\frac{2(\log n)^{3 N} e^{\tau}}{n}\right)^{1 / 2}
\end{aligned}
$$

which converges to 0 as $n \rightarrow \infty$. Thus, the second term of (2.64) is negligible.
Now let us deal with the first term of (2.64). Using (2.46) and the computation of $J_{1}(t)$ and $J_{2}(t)$ (the second line of (2.31) and (2.34)) in the proof of Lemma 1, we have

$$
\begin{aligned}
\sum_{t=0}^{t_{1}} \mathbf{P}\left(\mathcal{H}_{t}\right) & \sim \sum_{t=0}^{t_{1}} \exp \left(-\sum_{i=0}^{t-1} \frac{1}{n} r\left(\frac{i}{n}\right)\right) \\
& \sim \sum_{t=0}^{t_{1}} \exp \left(-J_{1}(t)-J_{2}(t)\right) \\
& \sim \sum_{t=0}^{t_{1}}\{y(t / n)(1-\log y(t / n))\}^{1 / 2} \exp \left(-J_{2}(t)\right) \\
& \sim \sum_{t=0}^{t_{1}}\{y(t / n)(1-\log y(t / n))\}^{1 / 2} \exp \left\{\frac{1}{2} \int_{0}^{\left.-\log y(t / n) \frac{\log \left(\frac{(1-a-\log y(t / n))(1+a)}{1-\log y(t / n)}\right)}{a e^{a}} d a\right\}}\right. \\
& \sim \int_{0}^{t_{1} / n}\{y(x)(1-\log y(x))\}^{1 / 2} \exp \left\{\frac{1}{2} \int_{0}^{\left.-\log y(x) \frac{\log \left(\frac{(1-a-\log y(x))(1+a)}{1-\log y(x)}\right)}{a e^{a}} d a\right\} d x}\right\}
\end{aligned}
$$

Now (2.6), (2.8) and (2.11) together imply

$$
\frac{d y}{d x}=-\frac{2}{1-\log y(x)}
$$

Using this and taking $y=y(x)$ as a new variable in the integral above, we get

$$
\begin{aligned}
\sum_{t=0}^{t_{1}} \mathbf{P}\left(\mathcal{H}_{t}\right) & \sim-\frac{1}{2} \int_{1}^{y\left(t_{1} / n\right)} y^{1 / 2}(1-\log y)^{3 / 2} \exp \left\{\frac{1}{2} \int_{0}^{-\log y \log \left(\frac{(1-a-\log y)(1+a)}{1-\log y}\right)} \underset{a e^{a}}{l} d a\right\} d y \\
& =\frac{1}{2} \int_{0}^{-\log y\left(t_{1} / n\right)}(1+\eta)^{3 / 2} \exp \left\{-\frac{3 \eta}{2}+\frac{1}{2} \int_{0}^{\eta} \frac{\log \left(\frac{(1-a+\eta)(1+a)}{1+\eta}\right)}{a e^{a}} d a\right\} d \eta \\
& \sim \frac{1}{2} \int_{0}^{\infty}(1+\eta)^{3 / 2} \exp \left\{-\frac{3 \eta}{2}+\frac{1}{2} \int_{0}^{\eta} \frac{\log \left(\frac{(1-a+\eta)(1+a)}{1+\eta}\right)}{a e^{a}} d a\right\} d \eta \\
& \approx 0.829 .
\end{aligned}
$$

Here in the third last step we set $\eta=-\log y$, and in the last step we used numerical integration. From this and (2.64) Theorem 3 follows immediately.

In the proof above we actually computed the asymptotic probability $\mathbf{P}\left(\mathcal{H}_{t}\right)$ that $G_{t}$ contains no cycle, for $t \leq t_{1}$. In fact, for $0 \leq x \leq t_{1} / n$, we have

$$
\mathbf{P}\left(\mathcal{H}_{t}\right) \sim \exp \left\{I(x)-\frac{\eta}{2}\right\} \sqrt{1+\eta}
$$

where $\eta=-\log y(x)$ and

$$
I(x)=\frac{1}{2} \int_{0}^{\eta} \frac{\log \left(\frac{(1-a+\eta)(1+a)}{1+\eta}\right)}{a e^{a}} d a .
$$

The graph of this function (as function of $x$ ) is shown in Figure 1 in Section 1. It is interesting that this graph is almost a circular shape.

## 3 Approximation of $Y$ and $Z$

The variables $Y$ and $Z$ are obviously crucial, so we examine them closely, for $t$ up until very nearly the end of the process.

Lemma 2 For $0 \leq t \leq n-40$, we have

$$
\begin{array}{r}
\left|\mathbf{E}\left(Y_{t+1}-Y_{t} \mid G_{t}\right)-f\left(\frac{t}{n}, \frac{Y_{t}}{n}\right)\right| \leq \frac{5}{n-t} \\
\left|\mathbf{E}\left(Z_{t+1}-Z_{t} \mid G_{t}\right)-g\left(\frac{t}{n}, \frac{Y_{t}}{n}, \frac{Z_{t}}{n}\right)\right| \leq \frac{20}{n-t} \tag{3.2}
\end{array}
$$

where $f$ and $g$ are the functions defined in (2.6) and (2.7), respectively. Moreover, for any $t \geq 0$,

$$
\begin{equation*}
Y_{t}+Z_{t}-2 \leq Y_{t+1}+Z_{t+1} \leq Y_{t}+Z_{t} . \tag{3.3}
\end{equation*}
$$

## Proof We have

$$
\left(Y_{t+1}-Y_{t}, Z_{t+1}-Z_{t}\right) \in\{(0,0),(0,-1),(0,-2),(-1,0),(-1,-1),(-2,1)\}
$$

and the number of sites contributing to these changes are $4\binom{n-t-Y_{t}-Z_{t}}{2}+\left(n-t-Y_{t}-Z_{t}\right)$, $4 Z_{t}\left(n-t-Y_{t}-Z_{t}\right), 4\binom{Z_{t}}{2}, 2 Y_{t}\left(n-t-Y_{t}-Z_{t}\right), 2 Y_{t} Z_{t}$ and $\binom{Y_{t}}{2}$, respectively. In particular, $Y_{t}+Z_{t}$ is non-increasing with $t$, and differs by at most 2 from $Y_{t+1}+Z_{t+1}$. Hence (3.3) is true. Also, $Y_{t}$ is non-increasing with $t$ and differs by at most 2 from $Y_{t+1}$. From the above it can be checked that the expected change of the number of isolates at time $t$ is $-\left(2 Y_{t} / U_{t}\right)-\left(2 Y_{t} Z_{t} / U_{t}\left(\binom{U_{t}}{2}-Z_{t}\right)\right)$. From (2.3) we have $\binom{U_{t}}{2}-Z_{t}=U_{t}^{2} / 2-(n-t-$ $\left.Y_{t} / 2\right)-Z_{t} \geq U_{t}^{2} / 2-\left(n-t-Y_{t} / 2\right)-\left(n-t-Y_{t}\right) \geq U_{t}\left(U_{t}-2\right) / 2 \geq(n-t)(n-t-2) / 2$. Using this and (2.3) one can show that the second term is bounded above in absolute value by $5 /(n-t)$ (assuming $n-t \geq 10$ ), whilst the first term is $f\left(t / n, Y_{t} / n\right)$ by (2.2). So (3.1) is proved. In each step of the process, $Z_{t}$ can remain unchanged, increase by 1 , or decrease by 1 or 2 , and the expected change of $Z_{t}$ is $\left(\binom{Y_{t}}{2}-2 Z_{t}\left(U_{t}-2\right)\right) /\left(\binom{U_{t}}{2}-Z_{t}\right)$. From this and by a similar estimation we get (3.2) for $n-t \geq 40$.

### 3.1 Phase 1: $t \leq t_{1}=n-\left\lceil(\log n)^{N}\right\rceil$

The approach taken is to use large deviation inequalities as in [9] to show that the variables approximately satisfy differential equations. The solutions of these differential equations possess a stability which is used to show that the variables continue to concentrate near these solutions far past the point reached by the argument for this random process in $[5,6]$.

We begin with some preliminary observations. Recall from (2.6) and (2.7) the functions $f(x, y)=-2 y /(2-2 x-y)$ and $g(x, y, z)=\left(y^{2}-4(2-2 x-y) z\right) /(2-2 x-y)^{2}$ in the differential equations (2.8) and (2.9). As before $y(x)$ and $z(x)$ denote the solutions of these equations. Then it is easy to see that

$$
\begin{equation*}
|f(x, y)| \leq 2,|g(x, y, z)| \leq 5 \tag{3.4}
\end{equation*}
$$

provided $y, z \in[0,1-x]$. Setting $p(x)=f(x, y(x))$ and $q(x)=g(x, y(x), z(x))$, then from (2.14) and (2.16) and estimating $d y / d x$ and $d z / d x$ using (3.4), we have

$$
\begin{equation*}
|p(x)| \leq 2,|q(x)| \leq 5 \tag{3.5}
\end{equation*}
$$

Moreover, it is easily checked that $|d p / d x| \leq 4 /(1-x)$ and $|d q / d x| \leq 56 /(1-x)$ for $0 \leq x<1$. Hence by the Mean Value Theorem we have

$$
\begin{align*}
\left|p\left(x_{1}\right)-p\left(x_{2}\right)\right| & \leq \frac{4}{1-x_{2}}\left|x_{1}-x_{2}\right|  \tag{3.6}\\
\left|q\left(x_{1}\right)-q\left(x_{2}\right)\right| & \leq \frac{56}{1-x_{2}}\left|x_{1}-x_{2}\right| \tag{3.7}
\end{align*}
$$

provided that $0 \leq x_{1} \leq x_{2}<1$.

Proof of Theorem 4 The proof uses the main idea in the proof of [9, Theorem 5.1]. But we need more accurate estimations and judicious choices of the step lengths when bounding large deviations, and the error in the approximation needs to decrease during the process.

We prove (2.21) first. Let $0=k_{0}<k_{1}<\cdots<k_{\ell}=k_{\ell}(n)$ be an integer time sequence such that $n-k_{\ell} \rightarrow \infty$ when $n \rightarrow \infty$. For $i=0,1, \ldots, \ell-1$, denote $w_{i}=k_{i+1}-k_{i}$ and let $\alpha_{i}>0$ be real numbers. At the moment we assume that $\left\{k_{i}\right\}$ and $\left\{\alpha_{i}\right\}$ are any sequences such that $\alpha_{i} \leq w_{i} \leq\left(n-k_{i}\right) / 4$ and $w_{i}<n-k_{i+1}$ for each $i$. Later we will choose $k_{i}$ 's and $\alpha_{i}$ 's in a particular way so that these conditions are satisfied. Denote

$$
h(n, i)=\frac{\left(n-k_{i}\right) w_{i}}{\left(n-k_{i+1}-w_{i}\right)^{2}} .
$$

Since $w_{i}<n-k_{i+1}$ by our assumption, we have $w_{i}<3\left(n-k_{i+1}\right)$ and using this one can check that

$$
\begin{equation*}
\frac{1}{n-k_{i+1}} \leq \frac{w_{i}}{n-k_{i+1}}<h(n, i) \tag{3.8}
\end{equation*}
$$

For each $t$ with $0 \leq t<w_{i}$, by the Mean Value Theorem there exist $\theta$ between $k_{i} / n$ and $\left(k_{i}+t\right) / n$ and $\psi$ between $Y_{k_{i}+t} / n$ and $Y_{k_{i}} / n$ such that

$$
\begin{align*}
\left|f\left(\frac{k_{i}+t}{n}, \frac{Y_{k_{i}+t}}{n}\right)-f\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}\right)\right| & =\frac{4}{(2(1-\theta)-\psi)^{2}}\left\{\psi \cdot \frac{t}{n}+(1-\theta) \cdot \frac{\left|Y_{k_{i}+t}-Y_{k_{i}}\right|}{n}\right\} \\
& \leq \frac{4}{\left(2\left(1-\frac{k_{i}+t}{n}\right)-\frac{Y_{k_{i}}}{n}\right)^{2}}\left\{\frac{Y_{k_{i}}}{n} \cdot \frac{t}{n}+\left(1-\frac{k_{i}}{n}\right) \cdot \frac{2 t}{n}\right\} \\
& \leq \frac{4}{\left(2\left(1-\frac{k_{i+1}}{n}\right)-\frac{n-k_{i}}{n}\right)^{2}}\left\{\frac{n-k_{i}}{n} \cdot \frac{w_{i}}{n}+\frac{n-k_{i}}{n} \cdot \frac{2 w_{i}}{n}\right\} \\
& =12 h(n, i) . \tag{3.9}
\end{align*}
$$

Here we use the facts that $\left|Y_{k_{i}+t}-Y_{k_{i}}\right| \leq 2 t$ and $Y_{k_{i}} \leq n-k_{i}$. From (3.1), (3.9) and (3.8) we then have

$$
\begin{align*}
\mathbf{E}\left(Y_{k_{i}+t+1}-Y_{k_{i}+t} \mid G_{k_{i}+t}\right) & \leq f\left(\frac{k_{i}+t}{n}, \frac{Y_{k_{i}+t}}{n}\right)+\frac{5}{n-k_{i}-t} \\
& \leq f\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}\right)+12 h(n, i)+\frac{5}{n-k_{i+1}} \\
& \leq f\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}\right)+17 h(n, i) . \tag{3.10}
\end{align*}
$$

For $t=0,1, \ldots, w_{i}$, set

$$
X_{t}=Y_{k_{i}+t}-Y_{k_{i}}-t f\left(k_{i} / n, Y_{k_{i}} / n\right)-17 t h(n, i) .
$$

Then (3.10) implies that $X_{0}, X_{1}, \ldots, X_{w_{i}}$ is a supermartingale (with respect to the sequence of $\sigma$-algebras generated by $\left.\left\{\left(G_{0}, G_{1}, \ldots, G_{t}\right)\right\}_{t \geq 0}\right)$ with $X_{0}=0$. As $Y_{k_{i}} \leq n-k_{i}$,
from (3.4) we have $\left|f\left(k_{i} / n, Y_{k_{i}} / n\right)\right| \leq 2$ and thus

$$
\left|X_{t+1}-X_{t}\right| \leq 4+17 h(n, i) .
$$

Therefore, from [9, Lemma 4.2] and since $\alpha_{i} \leq w_{i}$, it follows that, conditioned upon $G_{k_{i}}$,

$$
\begin{align*}
\left|Y_{k_{i+1}}-Y_{k_{i}}-w_{i} f\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}\right)\right| & <17 w_{i} h(n, i)+(4+17 h(n, i)) \sqrt{2 w_{i} \alpha_{i}} \\
& <51 w_{i} h(n, i)+4 \sqrt{2 w_{i} \alpha_{i}} \tag{3.11}
\end{align*}
$$

holds with probability at least $1-2 e^{-\alpha_{i}}$.
In the following we will show by induction that (2.21) holds at our chosen times $k_{i}$ with the desired probability. Set

$$
\begin{aligned}
& A_{1}=Y_{k_{i}}-n y\left(\frac{k_{i}}{n}\right) \\
& A_{2}=Y_{k_{i+1}}-Y_{k_{i}}-w_{i} f\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}\right) \\
& A_{3}=w_{i} p\left(\frac{k_{i}}{n}\right)+n y\left(\frac{k_{i}}{n}\right)-n y\left(\frac{k_{i+1}}{n}\right) \\
& A_{4}=w_{i} f\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}\right)-w_{i} p\left(\frac{k_{i}}{n}\right)
\end{aligned}
$$

so that $Y_{k_{i+1}}-n y\left(k_{i+1} / n\right)=A_{1}+A_{2}+A_{3}+A_{4}$. By the Mean Value Theorem and (3.6), (3.8), for some $\theta$ with $k_{i}<\theta<k_{i+1}$, we have

$$
\begin{align*}
\left|A_{3}\right| & =w_{i}\left|p\left(\frac{k_{i}}{n}\right)-p\left(\frac{\theta}{n}\right)\right| \\
& \leq \frac{4 w_{i}}{1-\frac{\theta}{n}}\left|\frac{\theta}{n}-\frac{k_{i}}{n}\right| \\
& \leq \frac{4 w_{i}^{2}}{n-k_{i+1}} \\
& \leq 4 w_{i} h(n, i) . \tag{3.12}
\end{align*}
$$

Also by the Mean Value Theorem, there exists some $\psi$ between $Y_{k_{i}} / n$ and $y\left(k_{i} / n\right)$ (hence $0 \leq \psi<1-k_{i} / n$ by (2.3) and (2.14)) such that

$$
\begin{aligned}
A_{4} & =w_{i} \cdot \frac{A_{1}}{n} \cdot \frac{\partial f}{\partial y}\left(\frac{k_{i}}{n}, \psi\right) \\
& =-\frac{4 w_{i}\left(1-\frac{k_{i}}{n}\right)}{n\left(2\left(1-\frac{k_{i}}{n}\right)-\psi\right)^{2}} A_{1} .
\end{aligned}
$$

Since we assume $w_{i} \leq\left(n-k_{i}\right) / 4$, it is clear that the coefficient of $A_{1}$ here is between -1 and 0 , and hence

$$
\begin{align*}
\left|A_{1}+A_{4}\right| & =\left(1-\frac{4 w_{i}\left(1-\frac{k_{i}}{n}\right)}{n\left(2\left(1-\frac{k_{i}}{n}\right)-\psi\right)^{2}}\right)\left|A_{1}\right| \\
& \leq \frac{n-k_{i+1}}{n-k_{i}}\left|A_{1}\right| . \tag{3.13}
\end{align*}
$$

Putting (3.11), (3.12) and (3.13) together, with probability at least $1-2 e^{-\alpha_{i}}$, we have conditional upon any graph $G_{k_{i}}$,

$$
\begin{equation*}
\left|Y_{k_{i+1}}-n y\left(k_{i+1} / n\right)\right| \leq \frac{n-k_{i+1}}{n-k_{i}}\left|A_{1}\right|+55 w_{i} h(n, i)+4 \sqrt{2 w_{i} \alpha_{i}} \tag{3.14}
\end{equation*}
$$

Note that this is true for each $i=0,1, \ldots, \ell-1$.
For each $i$ up to $\ell$, define

$$
\begin{equation*}
B_{i}=\sum_{j=1}^{i} \frac{n-k_{i}}{n-k_{j}} b_{j-1} \tag{3.15}
\end{equation*}
$$

with

$$
b_{j}=55 w_{j} h(n, j)+4 \sqrt{2 w_{j} \alpha_{j}}
$$

and note that $Y_{0}-n y(0)=0$. Consider conditioning for successive $i$ on the event

$$
\begin{equation*}
\left|Y_{k_{i}}-n y\left(k_{i} / n\right)\right| \leq B_{i}, \tag{3.16}
\end{equation*}
$$

with no conditioning in the case $i=0$. Then, for each $i$, we obtain (3.14) with conditional probability $1-2 e^{-\alpha_{i}}$. Thus, by induction and noting that $\left(\left(n-k_{i}\right) /\left(n-k_{i-1}\right)\right) B_{i-1}+b_{i-1}=$ $B_{i}$, for $0 \leq i \leq \ell$ we have

$$
\begin{equation*}
\mathbf{P}\left(\left|Y_{k_{i}}-n y\left(k_{i} / n\right)\right| \leq B_{i}\right) \geq \prod_{j=0}^{i-1}\left(1-2 e^{-\alpha_{j}}\right) \geq 1-2 \sum_{j=0}^{i-1} e^{-\alpha_{j}} \tag{3.17}
\end{equation*}
$$

Now we choose $k_{i}$ 's in the following way. Let $\beta$ be a real number with $0<\beta \leq 1 / 2$, and denote $F(t)=t-\left\lceil(n-t)^{\beta}\right\rceil$ for $0 \leq t<n$. Set $k_{0}=0$. Inductively suppose $k_{0}, \ldots, k_{i}$ have been chosen for some $i \geq 0$. If $F(\sigma(n))<k_{i}$ (that is, $\sigma(n)-k_{i}<\left\lceil(n-\sigma(n))^{\beta}\right\rceil$ ), then stop (this determines $\ell$ ); otherwise, since $F$ is strictly increasing with $t$, there exists a smallest integer $k_{i+1}$ such that $F\left(k_{i+1}\right) \geq k_{i}$. In this way we define a sequence $0=$ $k_{0}, k_{1}, \ldots, k_{\ell}(\leq \sigma(n))$, which is increasing since $F\left(k_{i}\right)<k_{i}$ implies $k_{i}<k_{i+1}$. Also, by definition we have $w_{i}=k_{i+1}-k_{i} \geq\left\lceil\left(n-k_{i+1}\right)^{\beta}\right\rceil \geq\left(n-k_{i+1}\right)^{\beta}$ and $F\left(k_{i+1}-1\right)<k_{i}$, which implies $w_{i}<1+\left\lceil\left(n-k_{i+1}+1\right)^{\beta}\right\rceil<2\left(n-k_{i+1}\right)^{\beta}$ as we assume $n-\sigma(n) \rightarrow \infty$. Hence, for $0 \leq i \leq \ell-1$, we have

$$
\begin{equation*}
\left(n-k_{i+1}\right)^{\beta} \leq w_{i}<2\left(n-k_{i+1}\right)^{\beta} \tag{3.18}
\end{equation*}
$$

which implies in particular that the requirements for the $k_{i}$ 's set at the beginning of the proof are satisfied. Moreover, for large $n$ we have

$$
\begin{equation*}
w_{i} h(n, i) \leq \frac{6 w_{i}^{2}}{n-k_{i+1}}<24\left(n-k_{i+1}\right)^{2 \beta-1} . \tag{3.19}
\end{equation*}
$$

Now for any $\varepsilon$ with $0<\varepsilon<1 / 4$, choose $\beta$ such that $0<2 \varepsilon<\beta \leq 1 / 2$. With this choice of $\beta$, define $k_{i}$ 's as above, and define

$$
\begin{equation*}
\alpha_{i}=\left(n-k_{i+1}\right)^{\beta-2 \varepsilon} \tag{3.20}
\end{equation*}
$$

for each $0 \leq i \leq \ell-1$, so that $\alpha_{i} \leq w_{i}$ is satisfied. Then (3.18) and (3.19) imply that $w_{i} h(n, i)<24 \sqrt{w_{i} \alpha_{i}}$, and hence $b_{i}<C \sqrt{w_{i} \alpha_{i}} / 2 \leq C\left(n-k_{i+1}\right)^{\beta-\varepsilon}, 0 \leq i \leq \ell-1$, where $C$ is an absolute constant (e.g. $C=1340$ ). Thus, by (3.18) we have for $0 \leq i \leq \ell$,

$$
\begin{aligned}
B_{i} & \leq C\left(n-k_{i}\right) \sum_{j=1}^{i} \frac{\left(n-k_{j}\right)^{\beta}}{\left(n-k_{j}\right)^{1+\varepsilon}} \\
& \leq C\left(n-k_{i}\right) \sum_{j=1}^{i} \frac{w_{j-1}}{\left(n-k_{j}\right)^{1+\varepsilon}} \\
& =C n^{1-\varepsilon}\left(1-\frac{k_{i}}{n}\right) \sum_{j=1}^{i} \frac{\frac{k_{j}}{n}-\frac{k_{j-1}^{n}}{n}}{\left(1-\frac{k_{j}}{n}\right)^{1+\varepsilon}} .
\end{aligned}
$$

The summation in this expression can be viewed as an upper Riemann sum of the increasing and convex function $1 /(1-x)^{1+\varepsilon}$ on the interval $\left[0, k_{i} / n\right]$. So it can be approximated by the integral $\int_{0}^{k_{i} / n} d x /(1-x)^{1+\varepsilon}$. The error for this approximation is at most as large as this integral itself. To see this it suffices to show that

$$
\frac{1}{\left(1-\frac{k_{j}}{n}\right)^{1+\varepsilon}}-\frac{1}{\left(1-\frac{k_{j-1}}{n}\right)^{1+\varepsilon}} \leq \frac{1}{\left(1-\frac{k_{j-1}}{n}\right)^{1+\varepsilon}}
$$

that is,

$$
\left(\frac{n-k_{j-1}}{n-k_{j}}\right)^{1+\varepsilon} \leq 2
$$

But this is guaranteed for large $n$ since (3.18) implies

$$
\frac{n-k_{j-1}}{n-k_{j}}<1+\frac{2}{\left(n-k_{j}\right)^{1-\beta}} \leq 1+\frac{2}{(n-\sigma(n))^{1-\beta}}
$$

and since $n-\sigma(n) \rightarrow \infty$. Therefore, for $0 \leq i \leq \ell$, we have

$$
\begin{equation*}
B_{i} \leq 2 C n^{1-\varepsilon}\left(1-\frac{k_{i}}{n}\right) \int_{0}^{k_{i} / n} \frac{d x}{(1-x)^{1+\varepsilon}}<\frac{2 C}{\varepsilon}\left(n-k_{i}\right)^{1-\varepsilon} . \tag{3.21}
\end{equation*}
$$

Now we estimate the bound in (3.17). By (3.18) we have $n-k_{i} \geq\left(n-k_{i+1}\right)^{\beta}+n-k_{i+1}>$ $n-k_{i+1}+1$ for $n$ sufficiently large, since $k_{i} \leq \sigma(n)$ implies $n-k_{i} \rightarrow \infty$. Thus, $\alpha_{i-1}>\alpha_{i}$
for $0 \leq i \leq \ell-1$. Therefore, noting that $\alpha_{\ell-1}=\left(n-k_{\ell}\right)^{\beta-2 \varepsilon} \geq(n-\sigma(n))^{\beta-2 \varepsilon}$, the right hand side of (3.17) is $1-O\left(e^{-\alpha_{\ell-1}}\right)=1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)$ for $\zeta=\beta-2 \varepsilon>0$ by (3.20).

We have now proved that $Y_{k_{i}}=n y\left(k_{i} / n\right)+2 C\left(n-k_{i}\right)^{1-\varepsilon} / \varepsilon$ holds with probability at least $1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)$, for each $i=0,1, \ldots, \ell$. This can easily be extended to $Y_{t}$ for $0 \leq t \leq \sigma(n)$. In fact, for $0 \leq t<k_{\ell}$ there exists a unique $i$ with $0 \leq i \leq \ell-1$ such that $k_{i} \leq t<k_{i+1}$. We have $\left|Y_{t}-Y_{k_{i}}\right| \leq 2\left(t-k_{i}\right)$ and $\left|y(t / n)-y\left(k_{i} / n\right)\right| \leq 2\left(t-k_{i}\right) / n$ (by the first inequality in (3.5) and the Mean Value Theorem) deterministically. So with probability at least $1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)$ we have

$$
\begin{aligned}
\left|Y_{t}-n y(t / n)\right| & \leq\left|Y_{t}-Y_{k_{i}}\right|+\left|Y_{k_{i}}-n y\left(k_{i} / n\right)\right|+n\left|y(t / n)-y\left(k_{i} / n\right)\right| \\
& \leq B_{i}+4\left(t-k_{i}\right) \\
& \leq B_{i}+4 w_{i} \\
& \leq B_{i}+8\left(n-k_{i+1}\right)^{\beta} \\
& \leq 2 C\left(n-k_{i}\right)^{1-\varepsilon} / \varepsilon+8\left(n-k_{i+1}\right)^{1-\varepsilon} \\
& <(6 C / \varepsilon+8)\left(n-k_{i+1}\right)^{1-\varepsilon} \\
& <(6 C / \varepsilon+8)(n-t)^{1-\varepsilon} .
\end{aligned}
$$

Here we used (3.18) and its consequence $n-k_{i} \leq 3\left(n-k_{i+1}\right)$, as well as the fact $\beta \leq 1-\varepsilon$ which follows from $0<2 \varepsilon<\beta \leq 1 / 2$. For $k_{\ell} \leq t \leq \sigma(n)$, by a similar argument we have

$$
\begin{aligned}
\left|Y_{t}-n y(t / n)\right| & \leq B_{\ell}+4\left(t-k_{\ell}\right) \\
& \leq B_{\ell}+4\left(\sigma(n)-k_{\ell}\right) \\
& <2 C\left(n-k_{\ell}\right)^{1-\varepsilon} / \varepsilon+8(n-\sigma(n))^{\beta} \\
& <(4 C / \varepsilon+8)(n-\sigma(n))^{1-\varepsilon} \\
& \leq(4 C / \varepsilon+8)(n-t)^{1-\varepsilon}
\end{aligned}
$$

with probability at least $1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)$. Here we used the fact $\sigma(n)-k_{\ell}<\left\lceil(n-\sigma(n))^{\beta}\right\rceil$ (which follows from the definition of $k_{\ell}$ ) and its consequence $n-k_{\ell}<2(n-\sigma(n))$. This completes the proof of (2.21), in which we may choose $C_{0}$ to be any number no less than $6 C / \varepsilon+8$.

The proof of (2.22) can be done in a similar manner. For $Z_{t}$ we will be conditioning on the analogue of (3.16) for $Z_{k_{i}}$, but also on the concentration given in (2.21) already established for $Y_{k_{i}}$ with high probability. This is because the function $g$ involves $y$ (note that $\left.g(x, y, z)=(f(x, y))^{2} / 4-4 z /(2-2 x-y)\right)$. Let $k_{i}$ 's and $\alpha_{i}$ 's be as above. For $0 \leq t<w_{i}$, using (3.9) and by an argument similar to the one used in its proof, one can check that

$$
\left|g\left(\frac{k_{i}+t}{n}, \frac{Y_{k_{i}+t}}{n}, \frac{Z_{k_{i}+t}}{n}\right)-g\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}, \frac{Z_{k_{i}}}{n}\right)\right| \leq 44 h(n, i) .
$$

This together with (3.2) and (3.8) then gives

$$
\begin{equation*}
\mathbf{E}\left(Z_{k_{i}+t+1}-Z_{k_{i}+t} \mid G_{k_{i}+t}\right) \leq g\left(\frac{k_{i}}{n}, \frac{Y_{k_{i}}}{n}, \frac{Z_{k_{i}}}{n}\right)+64 h(n, i) \tag{3.22}
\end{equation*}
$$

Define $A_{1}, A_{2}, A_{3}$, and $A_{4}$ in a way similar to the previous (replacing $f\left(k_{i} / n, Y_{k_{i}} / n\right)$, $y\left(k_{i} / n\right)$ and $p\left(k_{i} / n\right)$ by $g\left(k_{i} / n, Y_{k_{i}} / n, Z_{k_{i}} / n\right), z\left(k_{i} / n\right)$ and $q\left(k_{i} / n\right)$ respectively). By using a supermartingale and (3.22) we have $\left|A_{2}\right|<192 w_{i} h(n, i)+7 \sqrt{2 w_{i} \alpha_{i}}$ with probability at least $1-2 e^{-\alpha_{i}}$, and by using (3.7) we get $\left|A_{3}\right| \leq 56 w_{i} h(n, i)$. By the Mean Value Theorem (and using (2.16)) and (3.21) one can check that

$$
\begin{align*}
\left|A_{1}+A_{4}\right| & \leq \frac{n-k_{i+1}}{n-k_{i}}\left|A_{1}\right|+\frac{6 w_{i}}{n-k_{i}}\left|Y_{k_{i}}-n y\left(k_{i} / n\right)\right| \\
& \leq \frac{n-k_{i+1}}{n-k_{i}}\left|A_{1}\right|+\frac{12 C}{\varepsilon} w_{i}\left(n-k_{i}\right)^{-\varepsilon} \tag{3.23}
\end{align*}
$$

where $C$ is the absolute constant defined right after (3.20).
Here we are assuming that (2.21) holds for $t=k_{i}$, which we may do by imposing this extra restriction on the graph $G_{k_{i}}$ which is being conditioned upon in the inductive argument for $Z_{t}$. With the particular choices of $w_{i}$ and $\alpha_{i}$ as before, we have $w_{i}(n-$ $\left.k_{i}\right)^{-\varepsilon}<2\left(n-k_{i+1}\right)^{\beta}\left(n-k_{i}\right)^{-\varepsilon}<2\left(n-k_{i+1}\right)^{\beta-\varepsilon} \leq 2 \sqrt{w_{i} \alpha_{i}}$, and hence the extra term $12 C w_{i}\left(n-k_{i}\right)^{-\varepsilon} / \varepsilon$ in (3.23) does not cause any extra cost in our proof. So, conditioning on (2.21) holding for $t=k_{i}$, we have

$$
\left|Z_{k_{i+1}}-n z\left(k_{i+1} / n\right)\right| \leq \frac{n-k_{i+1}}{n-k_{i}}\left|Z_{k_{i}}-n z\left(k_{i} / n\right)\right|+C_{1} \sqrt{w_{i} \alpha_{i}} / 2
$$

with probability at least $1-2 e^{-\alpha_{i}}$, where $C_{1}=48 C / \varepsilon+6000$ for example.
Now define $B_{i}$ as in (3.15) but with $b_{j}=C_{1} \sqrt{w_{j} \alpha_{j}} / 2\left(\leq C_{1}\left(n-k_{j+1}\right)^{\beta-\varepsilon}\right)$. Condition for successive $i$ on the event that $\left|Z_{k_{i}}-n z\left(k_{i} / n\right)\right| \leq B_{i}$ and that (2.21) holds for $t=k_{i}$. The latter condition excludes a set of probability $O\left(e^{-(n-\sigma(n))^{5}}\right)$, using the result for $Y$. Then in place of (3.17) we have

$$
\begin{aligned}
\mathbf{P}\left(\left|Z_{k_{i}}-n z\left(k_{i} / n\right)\right| \leq B_{i}\right) & \geq \prod_{j=0}^{i-1}\left(1-2 e^{-\alpha_{j}}-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)\right) \\
& =\prod_{j=0}^{i-1}\left(1-2 e^{-\alpha_{j}}\right)\left(1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)\right) \\
& \geq\left(1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)\right) \prod_{j=0}^{i-1}\left(1-2 e^{-\alpha_{j}}\right) \\
& \geq\left(1-O\left(e^{-(n-\sigma(n))^{\varsigma}}\right)\right)\left(1-2 \sum_{j=0}^{i-1} e^{-\alpha_{j}}\right)
\end{aligned}
$$

Based on this, the rest of the proof of (2.22) is essentially the same as for (2.21) and hence is omitted. The constant $C_{0}$ in (2.22) can be any number no less than $6 C_{1} / \varepsilon+14$, and hence is applicable to (2.21) as well. The desired probability $1-O\left(e^{-(n-\sigma(n))^{1 / 2-2 \varepsilon}}\right)$ in Theorem 4 is obtained by setting $\beta=1 / 2$, specifically in $\zeta=\beta-2 \varepsilon$.

### 3.2 Phase 2: $t_{1}<t \leq n-2$

Proof of Theorem 5 We can bound the value of $Y$ for $t_{1}<t \leq t_{2}$ by considering the following events, where $t_{1} \leq s<i \leq t_{2}$ and $n-i \geq\lfloor(n-s) / 2\rfloor$ :

$$
\begin{aligned}
L_{i} & =\left\{\frac{Y_{i}+Z_{i}}{n-i}>\frac{2}{(\log n)^{\rho}}\right\} \\
J_{s, i} & =\left\{\frac{Y_{i}+Z_{i}}{n-i} \geq \frac{Y_{s}+Z_{s}}{n-s}(1+\beta(n)) \text { and } \frac{Y_{j}+Z_{j}}{n-j} \geq \frac{Y_{s}+Z_{s}}{n-s} \geq \frac{1}{(\log n)^{\rho}} \text { for } s \leq j<i\right\}
\end{aligned}
$$

where $\beta(n)=1 /(\log \log n)^{2}$. Suppose that

$$
Y_{t_{1}}+Z_{t_{1}}<\frac{n-t_{1}}{(\log n)^{\rho}}
$$

but that $L_{u}$ holds for some $u \leq t_{2}$. Choose $u$ to be minimum with this property. Then there is a minimum $v_{0}$ with $t_{1} \leq v_{0} \leq u$ such that $\left(Y_{i}+Z_{i}\right) /(n-i) \geq 1 /(\log n)^{\rho}$ for $v_{0} \leq i \leq u$. It follows that $\left(Y_{v_{0}-1}+Z_{v_{0}-1}\right) /\left(n-v_{0}+1\right)<1 /(\log n)^{\rho}$ and hence $\left(Y_{v_{0}}+\right.$ $\left.Z_{v_{0}}\right) /\left(n-v_{0}\right) \sim 1 /(\log n)^{\rho}$ since $Y_{v_{0}}+Z_{v_{0}} \leq Y_{v_{0}-1}+Z_{v_{0}-1}$ by the monotonicity of $Y+Z$. Defining inductively $n-v_{k}=\left\lfloor\left(n-v_{k-1}\right) / 2\right\rfloor$, we have $n-v_{k}<n-u$ for $k \geq k^{\prime}$, where $k^{\prime}=\left\lceil\log _{2}\left(\left(n-t_{1}\right) /(n-u)\right)\right\rceil=O(\log \log n)$. Thus the first inequality in $J_{s, i}$ must hold for some $s$ and $i$ with $v_{0} \leq s<i \leq u$ and $n-i \geq\lfloor(n-s) / 2\rfloor$, since otherwise

$$
\begin{aligned}
\frac{Y_{u}+Z_{u}}{n-u} & \leq \frac{Y_{v_{k^{\prime}-1}}+Z_{v_{k^{\prime}-1}}}{n-v_{k^{\prime}-1}}(1+\beta(n)) \\
& \vdots \\
& <\frac{Y_{v_{0}}+Z_{v_{0}}}{n-v_{0}}(1+\beta(n))^{k^{\prime}} \\
& =(\log n)^{-\rho}(1+\beta(n))^{O(\log \log n)} \\
& =(\log n)^{-\rho}(1+o(1)),
\end{aligned}
$$

contradicting $L_{u}$. Then we may assume that the inequalities $\left(Y_{j}+Z_{j}\right) /(n-j) \geq\left(Y_{s}+\right.$ $\left.Z_{s}\right) /(n-s), s \leq j<i$, in the definition of $J_{s, i}$ are satisfied since otherwise $s$ can be increased, holding $j$ fixed, until this is the case. Note that $\left(Y_{s}+Z_{s}\right) /(n-s) \geq(\log n)^{-\rho}$ by the choice of $v_{0}$. So all the inequalities in $J_{s, i}$ hold for such $s$ and $i$. In addition, by the minimality of $u, L_{s}$ does not hold. Hence for $u \leq t_{2}$ as above

$$
\begin{equation*}
L_{u} \wedge\left\{Y_{t_{1}}+Z_{t_{1}}<\frac{n-t_{1}}{(\log n)^{\rho}}\right\} \subseteq \bigvee_{\substack{\left.t_{1} \leq s \ll \leq t_{2} \\ n-i \geq(n-s) / 2\right\rfloor}}\left(J_{s, i} \wedge \overline{L_{s}}\right) \tag{3.24}
\end{equation*}
$$

We next show that for all $s$ and $i$ in the range given, $\mathbf{P}\left(J_{s, i} \wedge \overline{L_{s}}\right)=O\left((\log n)^{-K}\right)$ for all fixed $K>0$. This requires a tail bound for a random sequence such as $Y_{t}+Z_{t}$, which, with probability close to 1 , does not change in any given step. This is not easily accessible in the literature (though McDiarmid [2] has quite similar results for martingales) so we
give the following lemma. Here we use a supermartingale which with high probability, at least $1-O(\lambda)$, has a small difference, $O(\lambda)$ (where $\lambda \rightarrow 0$ ). The proof uses standard methods. In some sense it extends the argument in [4] which concerned the case that the sequence differences are independent and identically distributed.

Lemma 3 Let $X_{0}, \ldots, X_{r}$ be a supermartingale with respect to the process $G_{0}, \ldots, G_{r}$, with $X_{0}=0$. Let $C$ be a positive integer. Suppose that $W_{t}:=X_{t}-X_{t-1}$ takes on at most $C$ different values, $u_{j}(j=0, \ldots)$, and that $\left|u_{j}\right|<C$ for all $j$. Suppose furthermore that for some $0<\lambda<1$,
(i) $\mathbf{E}\left(W_{t}^{2} \mid G_{0}, \ldots, G_{t-1}\right)<\lambda$ for all $t \leq r$ and all $G_{0}, \ldots, G_{t-1}$,
(ii) $\left|u_{0}\right|<\lambda$,
(iii) $\mathbf{P}\left(W_{t} \neq u_{0} \mid G_{0}, \ldots, G_{t-1}\right)<\lambda$ for all $t \leq r$ and all $G_{0}, \ldots, G_{t-1}$.

Then for any $\alpha$ with $0<\alpha<\lambda r / C$,

$$
\mathbf{P}\left(X_{r} \geq \alpha\right)<\exp \left(-\alpha^{2} / 2 \lambda r+C^{3} \alpha^{3} / \lambda^{2} r^{2}\right) .
$$

Proof At first, fix $t$ and $G_{0}, \ldots, G_{t-1}$. Letting $p_{j}=\mathbf{P}\left(W_{t}=u_{j} \mid G_{0}, \ldots, G_{t-1}\right)$, we have $\left|h u_{j}\right|<1$ for $0<h<1 / C$ (to be chosen shortly) and so

$$
\mathbf{E}\left(e^{h W_{t}} \mid G_{0}, \ldots, G_{t-1}\right)=\sum_{j} p_{j} e^{h u_{j}}=1+h \sum_{j} p_{j} u_{j}+\frac{1}{2} h^{2} \sum_{j} p_{j} u_{j}^{2}+\phi h^{3} \sum_{j} p_{j} u_{j}^{3}
$$

where $|\phi|<1 / 2$, by Taylor's formula. The first summation is $\mathbf{E}\left(W_{t} \mid G_{0}, \ldots, G_{t-1}\right) \leq 0$ since $\left\langle X_{i}\right\rangle$ is a supermartingale. The second summation is $\mathbf{E}\left(W_{t}^{2} \mid G_{0}, \ldots, G_{t-1}\right)<\lambda$ by assumption (i). The third summation is at most $2 C^{3} \lambda$ by (ii) and (iii) and the assumptions about the $u_{j}$. So we have

$$
\begin{align*}
\log \mathbf{E}\left(e^{h W_{t}} \mid G_{0}, \ldots, G_{t-1}\right) & <\log \left(1+\frac{1}{2} h^{2} \lambda+h^{3} C^{3} \lambda\right) \\
& <\frac{1}{2} h^{2} \lambda+h^{3} C^{3} \lambda . \tag{3.25}
\end{align*}
$$

Now consider $0<\alpha<\lambda r / C$. Using Markov's inequality for the second step,

$$
\begin{aligned}
\mathbf{P}\left(X_{r} \geq \alpha\right) & =\mathbf{P}\left(e^{h X_{r}} \geq e^{h \alpha}\right) \\
& \leq e^{-h \alpha} \mathbf{E}\left(e^{h X_{r}}\right) \\
& =e^{-h \alpha} \mathbf{E}\left(e^{h X_{r-1}} e^{h W_{r}}\right) \\
& =e^{-h \alpha} \mathbf{E}\left(e^{h X_{r-1}} \mathbf{E}\left(e^{h W_{r}} \mid G_{0}, \ldots, G_{r-1}\right)\right) \\
& <\exp \left(-h \alpha+\frac{1}{2} h^{2} \lambda r+h^{3} C^{3} \lambda r\right)
\end{aligned}
$$

from (3.25) and by proceeding inductively. (Note: the second last step uses the fact that $\mathbf{E}(A B)=\mathbf{E}(A \mathbf{E}(B \mid C))$ for any random variables $A, B$ and $C$ with $A$ a function of $C$.) Selecting $h=\alpha / \lambda r$ to minimise the quadratic part, this becomes the bound in the lemma.

We will apply Lemma 3 to the event $J_{s, i}$, conditioning on $\overline{L_{s}}$, where $\lfloor(n-s) / 2\rfloor \leq$ $n-i \leq(\log n)^{N}$, for sufficiently large $n$. For all $G_{t}$, from the argument leading to (3.1) and (3.2), and noting (2.2) and (2.3), we have

$$
\begin{align*}
\mathbf{E}\left(Y_{t+1}+Z_{t+1}-Y_{t}-Z_{t} \mid G_{t}\right) & =-\frac{U_{t}\left(Y_{t}+2 Z_{t}\right)-Y_{t}\left(Y_{t}+1\right) / 2-4 Z_{t}}{\binom{U_{t}}{2}-Z_{t}} \\
& \leq-\frac{Y_{t}+Z_{t}}{n-t} . \tag{3.26}
\end{align*}
$$

Similarly,

$$
\begin{align*}
\mathbf{P}\left(Y_{t+1}+Z_{t+1}-Y_{t}-Z_{t} \neq 0 \mid G_{t}\right) & =\frac{U_{t}\left(Y_{t}+2 Z_{t}\right)-Y_{t}\left(Y_{t}+1\right) / 2-2 Z_{t}\left(Y_{t}+Z_{t}+1\right)}{\binom{U_{t}}{2}-Z_{t}} \\
& \leq \frac{U_{t}\left(Y_{t}+2 Z_{t}\right)}{\binom{U_{t}}{2}-Z_{t}} \\
& \leq \frac{2\left(Y_{t}+2 Z_{t}\right)}{U_{t}-2} \\
& \leq \frac{4\left(Y_{t}+Z_{t}\right)}{n-t} . \tag{3.27}
\end{align*}
$$

Here we used $\binom{U_{t}}{2}-Z_{t} \geq U_{t}\left(U_{t}-2\right) / 2$, which can be proved by using (2.3).
Let

$$
\mu=\frac{Y_{s}+Z_{s}}{n-s}
$$

Let $D_{0}(\mu), D_{1}(\mu), \ldots$ be independent copies of the random variable $D(\mu)$ with $\mathbf{P}(D(\mu)=$ $\mu)=1-\mu$ and $\mathbf{P}(D(\mu)=\mu-1)=\mu$. At this point, take $G_{s}$ fixed and consider the rest of the process, up to $G_{i}$. Note that for this process, we only need to condition on $G_{s+t}$ rather than $G_{s}, \ldots, G_{s+t}$, since they both determine the same induced probability for $\left(G_{s+t}, G_{s+t+1}, \ldots\right)$. We are only concerned with $s+t \leq i$, so for the lemma, $r=i-s$. Define for $t \geq 0$

$$
W_{t+1}= \begin{cases}\left(Y_{s+t+1}+Z_{s+t+1}\right)-\left(Y_{s+t}+Z_{s+t}\right)+\mu, & \text { if } Y_{s+t}+Z_{s+t} \geq(n-s-t) \mu \\ D_{t}(\mu), & \text { otherwise }\end{cases}
$$

and

$$
X_{0}=0, \quad X_{t+1}=X_{t}+W_{t+1} .
$$

If $Y_{s+t}+Z_{s+t} \geq(n-s-t) \mu$, then using (3.26) we have

$$
\mathbf{E}\left(W_{t+1} \mid G_{s+t}\right)=\mathbf{E}\left(Y_{s+t+1}+Z_{s+t+1}-Y_{s+t}-Z_{s+t} \mid G_{s+t}\right)+\mu \leq 0
$$

whilst if $Y_{s+t}<(n-s-t) \mu$ then $\mathbf{E}\left(W_{t+1} \mid G_{s+t}\right)=\mathbf{E} D(\mu)=0$. Thus $\left\langle X_{t}\right\rangle$ is a supermartingale with respect to $\left\langle G_{s+t}\right\rangle$. In addition, if $J_{s, i}$ holds, then $Y_{s+t}+Z_{s+t} \geq$ $(n-s-t) \mu$ for all $t$ with $0 \leq t \leq i-s$, and hence we get

$$
\begin{equation*}
X_{t}=Y_{s+t}+Z_{s+t}-Y_{s}-Z_{s}+t \mu \tag{3.28}
\end{equation*}
$$

by solving the difference equation $X_{t+1}-X_{t}=\left(Y_{s+t+1}+Z_{s+t+1}\right)-\left(Y_{s+t}+Z_{s+t}\right)+\mu$, $X_{0}=0$.

Note that $W_{t+1}=\mu, \mu-1$ or $\mu-2$ since $\left(Y_{s+t+1}+Z_{s+t+1}\right)-\left(Y_{s+t}+Z_{s+t}\right)=0,-1$ or -2 as mentioned in the paragraph following (2.4). So with $u_{0}=\mu$ and $\lambda=34 \mu$, we may let $C=3$ in Lemma 3 (for $n$ sufficiently large), and only the conditions (i) and (iii) still need to be checked (noting that $\lambda<1$ by $\overline{L_{s}}$ ). By (3.27) we have

$$
\mathbf{P}\left(W_{t+1} \neq u_{0} \mid G_{s+t}\right) \leq \frac{4\left(Y_{s+t}+Z_{s+t}\right)}{n-s-t} \leq \frac{8\left(Y_{s}+Z_{s}\right)}{n-s}=8 \mu<\lambda,
$$

for $n$ sufficiently large, using $n-s-t \geq n-i+1>(n-s) / 2$ and $Y_{s+t}+Z_{s+t} \leq Y_{s}+Z_{s}$. This gives (iii), and also implies

$$
\mathbf{E}\left(W_{t+1}^{2} \mid G_{s+t}\right)<\mu^{2}+\mathbf{P}\left(W_{t+1} \neq u_{0} \mid G_{s+t}\right) \max W_{t+1}^{2}<\mu^{2}+32 \mu<\lambda
$$

for $n$ sufficiently large, since then $\mu<1$ because $s \leq t_{2}$ and $\overline{L_{s}}$ holds. Thus part (i) of the lemma also holds.

We may now apply the lemma with $r=i-s$, under the condition $J_{s, i} \wedge \overline{L_{s}}$. Note that the first condition in the definition of $J_{s, i}$ implies by monotonicity of $Y+Z$ that $n-s \geq(1+\beta(n))(n-i)$ and hence

$$
r=i-s \geq \beta(n)(n-i)=(n-i) /(\log \log n)^{2} .
$$

Also note that $r<n-s-1 \leq 2(n-i)$, and $\lambda=34 \mu \geq 34 /(\log n)^{\rho}$, whilst $\overline{L_{s}}$ implies that $\lambda \leq 68 /(\log n)^{\rho}$. Thus, with both these assumptions,

$$
\frac{136(n-i)}{(\log n)^{\rho}} \geq \lambda r \geq \frac{34(n-i)}{(\log n)^{\rho}(\log \log n)^{2}}
$$

Since $n-i \geq n-t_{2} \geq \log n$, applying Lemma 3 with $\alpha=(n-i) /(\log n)^{(1+2 \rho) / 3}$ gives

$$
\mathbf{P}\left(X_{r} \geq \alpha \mid J_{s, i} \wedge \overline{L_{s}}\right)<\exp \left\{-\Theta\left(\frac{n-i}{(\log n)^{(2+\rho) / 3}}\right)\right\}<\exp \left\{-\Theta\left((\log n)^{(1-\rho) / 3}\right)\right\}
$$

This implies

$$
\begin{equation*}
\mathbf{P}\left(\left\{X_{r} \geq \alpha\right\} \wedge J_{s, i} \mid \overline{L_{s}}\right)<\exp \left\{-\Theta\left((\log n)^{(1-\rho) / 3}\right)\right\} \tag{3.29}
\end{equation*}
$$

as $\mathbf{P}(A \wedge B \mid C) \leq \mathbf{P}(A \mid B \wedge C)$ for any events $A, B, C$.
On the other hand, assuming $J_{s, i}$ and $\overline{L_{s}}$, by (3.28) we have

$$
X_{r}=Y_{i}+Z_{i}-Y_{s}-Z_{s}+r \mu \geq(1+\beta(n))(n-i) \mu-(n-i) \mu \geq \frac{\beta(n)(n-i)}{(\log n)^{\rho}} \geq \alpha
$$

for $n$ sufficiently large. Thus, $J_{s, i} \subseteq\left\{X_{r} \geq \alpha\right\} \wedge J_{s, i}$ conditioning on $\overline{L_{s}}$, and from (3.29) we have

$$
\mathbf{P}\left(J_{s, i} \wedge \overline{L_{s}}\right) \leq \mathbf{P}\left(J_{s, i} \mid \overline{L_{s}}\right)<\exp \left\{-\Theta\left((\log n)^{(1-\rho) / 3}\right)\right\} .
$$

Note that there are $O\left((\log n)^{2 N}\right)$ such events $J_{s, i} \wedge \overline{L_{s}}$. Note also that $G_{t_{1}} \in \mathcal{G}_{1}$ implies $Y_{t_{1}}+Z_{t_{1}}<\left(n-t_{1}\right) /(\log n)^{\rho}$. Thus, by (3.24) the probability that $L_{u}$ holds for some $u$ with $t_{1} \leq u \leq t_{2}$, given $G_{t_{1}} \in \mathcal{G}_{1}$, is $O\left((\log n)^{-K}\right)$ for all $K>0$. In view of (2.25), this proves Theorem 5 .

To prove Theorem 6 we first note the following consequence of [5, Lemma 3.1].
Lemma 4 Let $0 \leq t<n$, and suppose that $G$ is a graph such that $\mathbf{P}\left(G_{t}=G\right) \neq 0$. Let $v$ be a vertex of degree less than 2 in $G$. The probability that in a random 2-process, $v$ is not incident with any of $E_{t+1}, \ldots, E_{t^{\prime}}$, conditional upon $G_{t}=G$, is $O\left(\left(n-t^{\prime}+1\right) /(n-t)\right)$ as $n \rightarrow \infty$ uniformly over all $t^{\prime}>t$.

Proof of Theorem 6 Since $Y+Z$ is non-decreasing, (2.27) follows immediately from $G \in \mathcal{G}_{2}$. Applying Lemma 4 to $t=t_{2}$ and a graph $G \in \mathcal{G}_{2}$, the expected number of isolated vertices which remain isolated in $G_{t_{3}}$ is $O\left(\left(n-t_{3}\right) /\left(n-t_{2}\right) Y(G)\right)=O\left((\log n)^{\delta-\rho}\right)$. Hence (2.28) follows by the first moment principle. Since $Z_{t_{3}}<(\log n)^{1-\rho}$ by (2.27), the same argument gives (2.29).

Acknowledgment We would like to thank the referees for many suggestions to improve the presentation.
